(Received 27 January 2009; accepted 14 April 2009; published online 10 June 2009)

Given a group-invariant quasi-free state on the algebra of canonical commutation relations (CCR), we show how group averaging techniques can be used to obtain a symmetry-reduced CCR algebra and reduced quasi-free state. When the group is compact, this method of symmetry reduction leads to standard results which can be obtained using other methods. When the group is noncompact, the group averaging prescription relies on technically favorable conditions which we delineate. As an example, we consider symmetry reduction of the usual vacuum state for a Klein–Gordon field on Minkowski spacetime by a noncompact subgroup of the Poincaré group consisting of a 1-parameter family of boosts, a 1-parameter family of spatial translations and a set of discrete translations. We show that the symmetry-reduced CCR algebra and vacuum state correspond to that used by each of Berger, Husain, and Pierrri for the polarized Gowdy T^3 quantum gravity model. © 2009 American Institute of Physics. I. INTRODUCTION

Given a classical field theory on a manifold M , if the field equations are invariant under a Lie group G , then the equations admit a canonical symmetry reduction to a system of equations for fields on M/G defining G -invariant solutions of the original field equations.^{1,2} Other G -invariant structures associated with the field theory (e.g., Lagrangians and conserved currents) will, under favorable conditions, drop to define corresponding structures for the reduced theory on M/G .^{3–5} For nonlinear classical field theories, symmetry reduction is often the most effective method for obtaining explicit solutions to the field equations and for further analyzing the structure of the field theory. While the theory of symmetry reduction in classical field theories is quite well understood, in quantum field theory it appears that the general theory of symmetry reduction is not nearly so well developed. Nonetheless, quantum models based on symmetry reduction (usually performed at the classical level) are common in the literature—particularly literature related to quantum gravity (see, for example, Ref. 6).

Motivated by loop quantum gravity models based on various approaches to quantum symmetry reduction, Engle⁷ gave a careful analysis of the axisymmetry reduction in the free Klein–Gordon quantum field theory. Using canonical quantization methods, he considered three distinct ways of defining the symmetry-reduced quantum theory and he exposed the relative merits of each. He showed that one of these definitions is preferred in the sense that it leads to a complete commutation of the processes of symmetry reduction and canonical quantization as well as possessing other desirable physical features.

Here we examine symmetry reduction of quantum field theories from the algebraic point of view. We focus on reduction of the bosonic canonical commutation relations (CCR) algebra and the reduction of quasi-free states thereon. The CCR algebra is determined by a vector space \mathcal{S} and a symplectic form Ω , which can be viewed as representing the phase space of solutions to a set of linear field equations. The quasi-free states are determined by a scalar product μ on \mathcal{S} which bounds Ω . Suppose G is a Lie group acting on \mathcal{S} preserving Ω . Then G defines a group of

^{a)}Electronic mail: torre@cc.usu.edu.

automorphisms of the CCR algebra. We say that a quasi-free state is G -invariant if μ is also G -invariant. In this case, one expects Ω and μ to somehow induce a reduced symplectic form and a reduced scalar product on the G -invariant elements of \mathcal{S} and hence define a reduced CCR algebra and a reduced quasi-free state. The principal goal of this paper is to spell out this reduction process in some detail.

To perform the symmetry reduction we use group averaging techniques borrowed from work on constrained quantization and quantum Marsden–Weinstein reduction.^{8,9} Using group averaging, we give a prescription for symmetry reduction of CCR algebras and their quasi-free states. For reduction by compact groups, this prescription always works and gives standard results. In particular, in the case of the axisymmetry reduction in the Klein–Gordon field, the reduced CCR algebra and reduced vacuum state coincide with that of the usual canonical quantization of the symmetry-reduced classical field theory (as given, e.g., in Ref. 7). For noncompact groups, the success of the prescription depends on a number of technical issues which we delineate. These issues largely stem from the fact that, when the symmetry reduction group is noncompact, the group-invariant solutions to the field equations are generally not elements of the space of solutions of the field equations one uses to define Ω and μ . As an example, we consider a reduction of the massless Klein–Gordon field on Minkowski space by a noncompact subgroup of the Poincaré group consisting of a 1-parameter family of boosts, a 1-parameter family of spatial translations and a set of discrete spatial translations. We show that, with an appropriate choice for \mathcal{S} , the reduction of the CCR algebra and the vacuum state leads to the algebra and state introduced (apparently independently) by each of Berger, Husain, and Pierri (BHP) in their quantization of the polarized Gowdy \mathbf{T}^3 model in general relativity.^{10–12} This result illuminates the fact that dynamical evolution is not unitarily implemented in the Fock representation associated with the BHP vacuum state.^{13,14}

II. QUASI-FREE STATES ON THE CCR ALGEBRA

Quasi-free states are defined on the algebra of CCR, a C^* algebra which can be defined as follows. Fix a symplectic vector space (\mathcal{S}, Ω) , where \mathcal{S} is a real vector space and $\Omega: \mathcal{S} \times \mathcal{S} \rightarrow \mathbf{R}$ is a symplectic form (possibly degenerate) on \mathcal{S} . Typically (\mathcal{S}, Ω) represents the phase space of solutions to some linear field equations. The CCR algebra, denoted $\mathcal{A}(\mathcal{S}, \Omega)$, is generated by elements denoted by $W(\varphi)$, $\varphi \in \mathcal{S}$, which satisfy

$$W(\varphi)^* = W(-\varphi), \quad W(\varphi_1)W(\varphi_2) = \exp\left\{\frac{i}{2}\Omega(\varphi_1, \varphi_2)\right\}W(\varphi_1 + \varphi_2) \quad (2.1)$$

and is completed in a C^* norm, determined as follows (see Ref. 15 and references therein). If Ω is nondegenerate, the C^* norm is unique, in which case $\mathcal{A}(\mathcal{S}, \Omega)$ is the Weyl algebra. If Ω is degenerate, one may introduce the “minimal regular norm” to define $\mathcal{A}(\mathcal{S}, \Omega)$.

To define a quasi-free state on the CCR algebra, we choose an inner product $\mu: \mathcal{S} \times \mathcal{S} \rightarrow \mathbf{R}$ on \mathcal{S} satisfying for all $\varphi_1, \varphi_2 \in \mathcal{S}$

$$\frac{1}{2}|\Omega(\varphi_1, \varphi_2)| \leq \mu(\varphi_1, \varphi_1)^{1/2}\mu(\varphi_2, \varphi_2)^{1/2}. \quad (2.2)$$

Quasi-free states $\omega_\mu: \mathcal{A} \rightarrow \mathbf{C}$ are in one to one correspondence with such inner products via (see Ref. 15 and references therein)

$$\omega_\mu(W(\varphi)) = \exp\left\{-\frac{1}{2}\mu(\varphi, \varphi)\right\}. \quad (2.3)$$

The requirement (2.2) implies that Ω extends to a (possibly degenerate) symplectic form on the real Hilbert space \mathcal{S}_μ , the completion of \mathcal{S} with respect to the norm defined by μ . There exists a bounded, skew-adjoint operator A such that

$$\frac{1}{2}\Omega(\varphi_1, \varphi_2) = \mu(\varphi_1, A\varphi_2), \quad \varphi_1, \varphi_2 \in \mathcal{S}_\mu. \quad (2.4)$$

III. SYMMETRY REDUCTION BY GROUP AVERAGING

In this section we shall see that reduction of the CCR and quasi-free states by group averaging always works for compact G . For noncompact, unimodular G the success of the group averaging prescription largely depends on the choice of \mathcal{S} .

We begin with a smooth, faithful group action $\Phi: G \times \mathcal{S} \rightarrow \mathcal{S}$, where G is a finite-dimensional Lie group. We assume that the group action preserves the symplectic form and the inner product,

$$\Omega(\Phi_g \cdot \varphi_1, \Phi_g \cdot \varphi_2) = \Omega(\varphi_1, \varphi_2), \quad (3.1)$$

$$\mu(\Phi_g \cdot \varphi_1, \Phi_g \cdot \varphi_2) = \mu(\varphi_1, \varphi_2), \quad \forall g \in G, \quad \varphi_1, \varphi_2 \in \mathcal{S}. \quad (3.2)$$

Thus G acts symplectically and orthogonally on $(\mathcal{S}, \Omega, \mu)$ and defines a group of *-automorphisms of $\mathcal{A}(\mathcal{S}, \Omega)$.¹⁵ We remark that the G -invariance of Ω and nondegeneracy of μ imply that the bounded operators Φ_g and A commute,

$$[A, \Phi_g] = 0, \quad \forall g \in G. \quad (3.3)$$

This follows from

$$\Omega(\Phi_g \cdot \varphi_1, \Phi_g \cdot \varphi_2) = 2\mu(\varphi_1, \Phi_g^\dagger A \Phi_g \varphi_2) \quad (3.4)$$

and (3.1), which imply

$$\mu(\varphi_1, A \varphi_2 - \Phi_g^\dagger A \Phi_g \varphi_2) = 0, \quad \forall \varphi_1, \varphi_2, \quad (3.5)$$

hence

$$A \Phi_g = \Phi_g A. \quad (3.6)$$

We formally define averaged bilinear forms via integration with respect to a fixed Haar measure dg ,

$$\Omega_G(\varphi_1, \varphi_2) = \int_G dg \Omega(\varphi_1, \Phi_g \cdot \varphi_2), \quad \mu_G(\varphi_1, \varphi_2) = \int_G dg \mu(\varphi_1, \Phi_g \cdot \varphi_2). \quad (3.7)$$

The integrands are continuous functions of $g \in G$. For compact G , these functions are bounded and the integrals exist for all $\varphi_1, \varphi_2 \in \mathcal{S}$. For noncompact G , we must assume that \mathcal{S} has been chosen such that the integrals exist for all $\varphi_1, \varphi_2 \in \mathcal{S}$.

If the measure is bi-invariant, i.e., G is unimodular, then the averaged bilinear forms Ω_G and μ_G inherit the algebraic symmetries of Ω and μ , respectively. For example,

$$\mu_G(\varphi_2, \varphi_1) = \int_G dg \mu(\varphi_2, \Phi_g \cdot \varphi_1) \quad (3.8)$$

$$= \int_G dg \mu(\Phi_g \cdot \varphi_1, \varphi_2) \quad (3.9)$$

$$= \int_G dg \mu(\varphi_1, \Phi_{g^{-1}} \varphi_2) \quad (3.10)$$

$$= \int_G dg^{-1} \mu(\varphi_1, \Phi_g \varphi_2) \quad (3.11)$$

$$= \int_G dg \mu(\varphi_1, \Phi_g \varphi_2) \quad (3.12)$$

$$= \mu_G(\varphi_1, \varphi_2), \quad (3.13)$$

where we used the fact that $dg^{-1} = dg$ for a bi-invariant measure. A similar computation establishes the skew symmetry of Ω_G . All compact Lie groups are unimodular. In the noncompact case, we henceforth restrict to unimodular groups. (It should be possible to generalize our considerations to certain nonunimodular groups, but subtleties arise related to the principle of symmetric criticality (Refs. 3–5) so we leave that investigation for future work.)

The bi-invariance of the measure dg also implies that, for any $h \in G$,

$$\mu_G(\varphi_1, \Phi_h \cdot \varphi_2) = \mu_G(\varphi_1, \varphi_2), \quad \Omega_G(\varphi_1, \Phi_h \cdot \varphi_2) = \Omega_G(\varphi_1, \varphi_2). \quad (3.14)$$

For example,

$$\Omega_G(\varphi_1, \Phi_h \cdot \varphi_2) = \int_G dg \Omega(\varphi_1, \Phi_g \Phi_h \cdot \varphi_2) \quad (3.15)$$

$$= \int_G dg \Omega(\varphi_1, \Phi_{gh} \cdot \varphi_2) \quad (3.16)$$

$$= \int_G d(gh) \Omega(\varphi_1, \Phi_{gh} \cdot \varphi_2) \quad (3.17)$$

$$= \Omega_G(\varphi_1, \varphi_2), \quad (3.18)$$

with a similar computation for μ_G . Hence the bilinear forms are degenerate: there exist null vectors given by

$$\varphi = (\Phi_h - 1)\psi \quad (3.19)$$

for any $h \in G$ and $\psi \in \mathcal{S}$. Denote the null spaces of μ_G and Ω_G by \mathcal{N}_μ and \mathcal{N}_Ω , respectively. For the group averaging prescription to work, we require that

$$\mathcal{N}_\mu \subset \mathcal{N}_\Omega, \quad (3.20)$$

so that μ_G and Ω_G define reduced bilinear forms, respectively, $\hat{\mu}$ and $\hat{\Omega}$, on $\hat{\mathcal{S}} = \mathcal{S} / \mathcal{N}_\mu$.

For compact G , (3.20) is always satisfied and, with the Haar measure normalized to unity, the reduced bilinear forms are precisely the restriction of Ω and μ to the set $\hat{\mathcal{S}} \subset \mathcal{S}$ of G -invariant fields (these fields appear in \mathcal{S} as the trivial representation of G), where $\hat{\varphi} \in \hat{\mathcal{S}}$ satisfies $\Phi_g \hat{\varphi} = \hat{\varphi}$, $\forall g \in G$. To prove this, it is convenient to work on the completion, \mathcal{S}_μ , of \mathcal{S} with respect to the norm defined by μ . We have the orthogonal decomposition

$$\mathcal{S}_\mu = \hat{\mathcal{S}}_\mu \oplus \hat{\mathcal{S}}_\mu^\perp. \quad (3.21)$$

μ_G extends to a bounded bilinear form on \mathcal{S}_μ whence there exists a $\psi \in \mathcal{S}_\mu$ such that

$$\mu_G(\varphi_1, \varphi_2) = \mu(\varphi_1, \psi). \quad (3.22)$$

From (3.14), it follows that ψ is G -invariant, whence

$$\mu_G(\varphi_1, \varphi_2) = \mu_G(\hat{\varphi}_1, \varphi_2) \quad (3.23)$$

and

$$\mu_G(\varphi_1, \varphi_2) = \int_G dg \mu(\Phi_g^{-1} \hat{\varphi}_1, \varphi_2) \quad (3.24)$$

$$= \int_G dg \mu(\hat{\varphi}_1, \varphi_2) \quad (3.25)$$

$$= \mu(\hat{\varphi}_1, \hat{\varphi}_2), \quad (3.26)$$

where $\hat{\varphi}_1, \hat{\varphi}_2$ are the components of φ_1, φ_2 along \hat{S}_μ . Evidently, on \mathcal{S}_μ the null space of μ_G is precisely \hat{S}_μ^\perp . On the quotient $\hat{S}_\mu = \mathcal{S}_\mu / \hat{S}_\mu^\perp$, the form μ_G is nondegenerate. Restricting to $\hat{S} \subset \hat{S}_\mu$, we obtain the reduced, positive-definite inner product on \hat{S}

$$\hat{\mu}(\hat{\varphi}_1, \hat{\varphi}_2) = \mu(\hat{\varphi}_1, \hat{\varphi}_2). \quad (3.27)$$

Similarly, on \mathcal{S}_μ the null space of Ω_G includes \hat{S}_μ^\perp , whence (on \mathcal{S}) Ω drops to define a (possibly degenerate) symplectic form $\hat{\Omega}$ on \hat{S} given by

$$\hat{\Omega}(\hat{\varphi}_1, \hat{\varphi}_2) = \Omega(\hat{\varphi}_1, \hat{\varphi}_2). \quad (3.28)$$

From (2.2) we have

$$\frac{1}{2} |\hat{\Omega}(\hat{\varphi}_1, \hat{\varphi}_2)| \leq \hat{\mu}(\hat{\varphi}_1, \hat{\varphi}_1)^{1/2} \hat{\mu}(\hat{\varphi}_2, \hat{\varphi}_2)^{1/2}, \quad (3.29)$$

so that the $\hat{\mu}$ defines a quasi-free state $\hat{\omega}$ on $\mathcal{A}(\hat{S}, \hat{\Omega})$. We say that $\hat{\omega}$ is the symmetry-reduced state on the reduced algebra $\mathcal{A}(\hat{S}, \hat{\Omega})$.

For noncompact G , we cannot expect any elements of \mathcal{S} (save the zero vector) to be G -invariant (see Sec. V), and none of the results from the previous paragraph need hold *a priori*. However, under favorable circumstances, a suitable choice of \mathcal{S} can be found such that the group average converges, (3.20) holds, and we can define $\hat{\Omega}$ and $\hat{\mu}$ on \hat{S} . If, in addition, $\hat{\mu} \geq 0$ and satisfies (3.29), then the group averaging will define a reduced quasi-free state on $\mathcal{A}(\hat{S}, \hat{\Omega})$. Although it appears there is no guarantee that a suitable choice of \mathcal{S} need exist in general, in Sec. V we shall see how the prescription goes through in a nontrivial case.

Finally, we note that the bi-invariant measure dg is only unique up to rescaling by a positive constant. Hence we actually obtain from the above prescription a 1-parameter family of reduced forms $\hat{\Omega}$ and $\hat{\mu}$ and hence a 1-parameter family of reduced CCR algebras and reduced quasi-free states. However it is straightforward to check that all these algebras are isomorphic with the isomorphisms identifying each of the corresponding quasi-free states.

IV. EXAMPLE: AXISYMMETRIC KLEIN–GORDON FIELD

Here we briefly consider the example studied by Engle,⁷ involving a compact symmetry group. The symmetry-reduced bilinear forms correspond to the Fock representation of the CCR for the symmetry-reduced classical theory, as given in Ref. 7.

Let (\mathbf{M}, η) be 3+1 Minkowski spacetime with inertial coordinates

$$x^\alpha = (t, \vec{x}) = (t, x, y, z), \quad (4.1)$$

and metric

$$\eta = -dt \otimes dt + dx \otimes dx + dy \otimes dy + dz \otimes dz. \quad (4.2)$$

We define \mathcal{S} to be the set of solutions to the Klein–Gordon equation,

$$(\square - m^2)\varphi = -\varphi_{,tt} + \varphi_{,xx} + \varphi_{,yy} + \varphi_{,zz} - m^2\varphi = 0, \quad (4.3)$$

whose Cauchy data on $t=\text{const}$ hyperplanes are smooth and rapidly decreasing at infinity (elements of Schwarz space). A more explicit representation of elements of \mathcal{S} is given by

$$\varphi(t, \vec{x}) = \int_{\mathbf{R}^3} d^3k \sqrt{\frac{1}{2\omega(2\pi)^3}} (a(\vec{k})e^{i\vec{k}\cdot\vec{x} - i\omega t} + \text{c.c.}), \quad \omega = \sqrt{k^2 + m^2}, \quad (4.4)$$

where $a(\vec{k})$ is a smooth and rapidly decreasing complex-valued function on \mathbf{R}^3 . The standard Klein–Gordon symplectic form is given by

$$\Omega(\varphi_1, \varphi_2) = \int_{\Sigma} \sqrt{\gamma}(\varphi_2 L_n \varphi_1 - \varphi_1 L_n \varphi_2) = \int_{\mathbf{R}^3} d^3k i(a_1^*(\vec{k})a_2(\vec{k}) - a_1(\vec{k})a_2^*(\vec{k})), \quad (4.5)$$

where n is the future pointing unit normal to the (arbitrary) spacelike hypersurface Σ with induced metric γ .

The symmetry group, $G=S^1$, acts via rotations about the z axis,

$$\Phi_\alpha \cdot \varphi(t, x, y, z) = \varphi(t, x \cos \alpha - y \sin \alpha, y \cos \alpha + x \sin \alpha, z). \quad (4.6)$$

As a subgroup of the Poincaré group, G clearly acts on \mathcal{S} and preserves the symplectic form. The set $\hat{\mathcal{S}} \subset \mathcal{S}$ of G -invariant fields is easily seen to be obtained from the solutions $\chi = \chi(t, r, z)$ to

$$-\chi_{,tt} + \frac{1}{r}(r\chi_{,r})_{,r} + \chi_{,zz} - m^2\chi = 0 \quad (4.7)$$

on $\mathbf{M}/G = \mathbf{R} \times \mathbf{R}^+ \times \mathbf{R}$ via

$$\hat{\varphi}(t, x, y, z) = \chi(t, \sqrt{x^2 + y^2}, z) \quad (4.8)$$

along with the restriction to smooth solutions with rapidly decreasing Cauchy data. The group-invariant fields can be expressed as

$$\hat{\varphi}(t, \vec{x}) = \int_0^\infty d\kappa \int_{-\infty}^\infty dk_z \sqrt{\frac{\kappa}{4\pi\omega}} \{A(\kappa, k_z) J_0(\kappa r) e^{i(k_z z - \omega t)} + \text{c.c.}\}, \quad (4.9)$$

where J_0 is the zeroth-order Bessel function,

$$r = \sqrt{x^2 + y^2}, \quad \omega = \sqrt{\kappa^2 + k_z^2 + m^2}, \quad (4.10)$$

and $A(\kappa, k_z)$ is related to $a(k_x, k_y, k_z)$ via

$$A(\kappa, k_z) = \frac{1}{2\pi} \sqrt{\kappa} \int_0^{2\pi} d\beta a(\kappa \cos \beta, \kappa \sin \beta, k_z). \quad (4.11)$$

The usual Poincaré invariant Fock vacuum state is defined by

$$\mu(\varphi_1, \varphi_2) = \int d^3k \frac{1}{2} (a_1^*(\vec{k})a_2(\vec{k}) + a_1(\vec{k})a_2^*(\vec{k})). \quad (4.12)$$

It is easily verified that μ is G -invariant as it must be since G is a subgroup of the Poincaré group.

As described in Sec. III, the symmetry-reduced bilinear forms $\hat{\Omega}$ and $\hat{\mu}$ can be computed either by averaging over the group (with normalized measure) or by restricting Ω and μ to the G -invariant fields (4.9). In either case we obtain

$$\hat{\Omega}(\hat{\varphi}_1, \hat{\varphi}_2) = 2\pi i \int_0^\infty d\kappa \int_{-\infty}^\infty dk_z (A_1^*(\kappa, k_z) A_2(\kappa, k_z) - A_1(\kappa, k_z) A_2^*(\kappa, k_z)), \quad (4.13)$$

$$\hat{\mu}(\hat{\varphi}_1, \hat{\varphi}_2) = \pi \int_0^\infty d\kappa \int_{-\infty}^\infty dk_z (A_1^*(\kappa, k_z) A_2(\kappa, k_z) + A_1(\kappa, k_z) A_2^*(\kappa, k_z)). \quad (4.14)$$

It is straightforward to check that the quasi-free state defined by $\hat{\mu}$ on $\mathcal{A}(\hat{\mathcal{S}}, \hat{\Omega})$ and its associated Gel'fand-Naimark-Segal (GNS) representation¹⁵ coincide with the usual quantization of the reduced classical field theory as described, e.g., in Ref. 7, where $\hat{\mu}$ defines the symmetry-reduced Fock vacuum.

V. EXAMPLE: BHP VACUUM STATE

Here we consider reduction of the massless Klein–Gordon field by a noncompact, disconnected subgroup of the Poincaré group. Besides providing a nontrivial illustration of the prescription described in Sec. III, this example has a couple of novel features. First, it shows how reduction by a disconnected group can allow one to drop the algebra and quasi-free states to that of a field theory on a compactified manifold. Second, it shows that one may interpret a well-studied state appearing in the quantum gravity “polarized Gowdy model” in terms of a reduction of the usual Poincaré invariant Fock vacuum for a massless Klein–Gordon field in Minkowski spacetime. This interpretation provides a simple argument for the lack of unitary implementability of time evolution in the Fock quantization of the Gowdy model defined by this state.

We begin by describing the group action and characterizing the group-invariant fields. We start with Minkowski spacetime as described in (4.1) and (4.2). Let $M \subset \mathbf{M}$ be the globally hyperbolic region $t > 0$, $t^2 - y^2 > 0$, equipped with the metric (4.2) restricted to M . Consider the group $G = \mathbf{Z} \times \mathbf{R}^2$ consisting of (i) translations in x by integral multiples of 2π , (ii) boosts along y , and (iii) translations in z . It is easy to verify that this group acts on M . The manifold of orbits, $\hat{M} = M/G$, is defined by the identifications,

$$x \sim x + 2\pi, \quad \tanh^{-1}\left(\frac{y}{t}\right) \sim \tanh^{-1}\left(\frac{y}{t}\right) + \text{const}, \quad z \sim z + \text{const}. \quad (5.1)$$

We have $\hat{M} \approx \mathbf{R}^+ \times \mathbf{S}^1$. To see this, consider the diffeomorphism mapping $(\tau, \sigma, \eta, \xi) \in \mathbf{R}^+ \times \mathbf{R}^3$ to $(t, x, y, z) \in M$ defined by

$$t = \tau \cosh \eta, \quad x = \sigma, \quad y = \tau \sinh \eta, \quad z = \xi. \quad (5.2)$$

In the $(\tau, \sigma, \eta, \xi)$ variables, the group action on M is defined by $(n, \alpha, \beta) \in \mathbf{Z} \times \mathbf{R}^2$,

$$\sigma \rightarrow \sigma + 2\pi n, \quad \eta \rightarrow \eta + \alpha, \quad \xi \rightarrow \xi + \beta, \quad n \in \mathbf{Z}, \quad \alpha, \beta \in \mathbf{R}, \quad (5.3)$$

whence the quotient space is $\mathbf{R}^+ \times \mathbf{S}^1$. The flat metric on M is G -invariant and drops to a flat metric $\hat{\eta}$ on \hat{M} given by

$$\eta = -d\tau \otimes d\tau + d\sigma \otimes d\sigma, \quad (5.4)$$

where we identify $\sigma \sim \sigma + 2\pi$. G -invariant solutions $\hat{\varphi}$ of the massless Klein–Gordon equation [(4.3) with $m=0$] are determined by functions $\psi = \psi(\tau, \sigma)$ on \hat{M} satisfying

$$-\psi_{,\tau\tau} - \frac{1}{\tau} \psi_{,\tau} + \psi_{,\sigma\sigma} = 0 \quad (5.5)$$

via

$$\hat{\varphi}(t, x, y, z) = \psi(\sqrt{t^2 - y^2}, x). \quad (5.6)$$

The reduced field equation (5.5) on \hat{M} is precisely the wave equation satisfied by the scalar field in the polarized Gowdy $\mathbf{R} \times \mathbf{T}^3$ spacetime metric by virtue of the symmetry-reduced vacuum Einstein equations and an appropriate choice of gauge.¹⁰ The symmetry-reduced Einstein–Hilbert Lagrangian determines a symplectic form on the space of smooth solutions to (5.5) and hence a CCR algebra [see (5.24) and (5.25), below]. Two representations of this algebra, based on a pair of algebraic vacuum states, have been studied in some detail in the literature.^{10–14,16} We shall recover one of these states—the BHP state—via group averaging.

We define \mathcal{S} as the set of solutions to the massless Klein–Gordon equation with compactly supported Cauchy data in M . The G -invariant symplectic form Ω is given by (4.5). The resulting CCR algebra $\mathcal{A}(\mathcal{S}, \Omega)$ is the Weyl algebra of the massless Klein–Gordon field restricted to M . The scalar product (4.12) defining the Poincaré invariant Fock vacuum state restricts to \mathcal{S} to define a G -invariant quasi-free state in $\mathcal{A}(\mathcal{S}, \Omega)$. There will be no G -invariant fields in \mathcal{S} since fields of the form (5.6) do not vanish as $|\vec{x}| \rightarrow \infty$. Nevertheless, G is unimodular and acts on \mathcal{S} preserving Ω and μ , so we may attempt to reduce the CCR algebra and the quasi-free state using group averaging.

It will be convenient to view the bilinear forms μ and Ω , defined in (4.5) and (4.12) for the set of solutions of (4.4) (with $m=0$), as real and imaginary parts of

$$\mathcal{B}(\varphi_1, \varphi_2) = i \int_{t=0} d^3x (\Phi_1^* \Phi_{2,t} - \Phi_{1,t}^* \Phi_2), \tag{5.7}$$

where Φ is the “positive frequency” part of φ ,

$$\varphi(t, \vec{x}) = \int d^3k \sqrt{\frac{1}{2\omega(k)(2\pi)^3}} (a(\vec{k}) e^{i\vec{k}\cdot\vec{x} - i\omega(k)t} + \text{c.c.}), \quad \omega(k) = \sqrt{k^2}, \tag{5.8}$$

$$\Phi = \int d^3k \sqrt{\frac{1}{2\omega(k)(2\pi)^3}} a(\vec{k}) e^{i\vec{k}\cdot\vec{x} - i\omega(k)t}, \tag{5.9}$$

and

$$\Omega(\varphi_1, \varphi_2) = -2 \operatorname{Im}[\mathcal{B}(\varphi_1, \varphi_2)], \quad \mu(\varphi_1, \varphi_2) = \operatorname{Re}[\mathcal{B}(\varphi_1, \varphi_2)]. \tag{5.10}$$

With $g=(n, \alpha, \beta)$, we have

$$\begin{aligned} \mathcal{B}(\varphi_1, \Phi_g \varphi_2) &= \int_{\mathbf{R}^3} d^3k \int_{\mathbf{R}^3} d^3l \int_{\mathbf{R}^3} d^3x \frac{1}{2(2\pi)^3} \sqrt{\frac{1}{\omega(k)\omega(l)}} a_1^*(\vec{l}) a_2(\vec{k}) \times [\omega(l) + \omega(k) \cosh(\alpha) \\ &\quad - k^y \sinh(\alpha)] e^{2\pi i k^x n + i k^z \beta} \times \exp\{i(k^x - l^x)x + i(k^z - l^z)z + iy[\cosh(\alpha)k^y - \sinh(\alpha)\omega(k) \\ &\quad - l^y]\}. \end{aligned}$$

The x, y, z, l^x, l^y, l^z integrals are easily performed; after some simplification, we have

$$\mathcal{B}(\varphi_1, \Phi_g \varphi_2) = - \int_{\mathbf{R}^3} d^3k \sqrt{\frac{1}{\omega(k)\omega(k, \alpha)}} a_1^*(k^x, l^y(\alpha), k^z) a_2(\vec{k}) \frac{dl^y(\alpha)}{d\alpha} e^{2\pi i k^x n + i k^z \beta}, \tag{5.11}$$

where now we define

$$l^y(\alpha) = k^y \cosh(\alpha) - \omega(k) \sinh(\alpha), \quad \omega(k, \alpha) = \sqrt{k^{x2} + l^y(\alpha)^2 + k^{z2}}. \tag{5.12}$$

The group average of \mathcal{B} takes the form

$$\int_G dg \mathcal{B}(\varphi_1, \Phi_g \varphi_2) = - \sum_{n=-\infty}^{\infty} \int_{-\infty}^{\infty} d\alpha \int_{-\infty}^{\infty} d\beta \int_{\mathbf{R}^3} d^3k \sqrt{\frac{1}{\omega(k)\omega(k, \alpha)}} \\ \times a_1^*(k^x, l^y(\alpha), k^z) a_2(\vec{k}) \frac{dl^y(\alpha)}{d\alpha} e^{2\pi i k^x n + i k^z \beta}. \quad (5.13)$$

The group average can be evaluated as follows. The sum over n defines the periodic delta function: for a smooth, rapidly decreasing function $f(u)$ we have

$$\int_{-\infty}^{\infty} du \sum_{n=-\infty}^{\infty} e^{2\pi i n u} f(u) = \sum_{n=-\infty}^{\infty} f(n). \quad (5.14)$$

The integral over β defines the ordinary delta function: for a smooth, rapidly decreasing function $f(u)$ we have

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} du \int_{-\infty}^{\infty} dv e^{i v u} f(u) = f(0). \quad (5.15)$$

We then get

$$\int_G dg \mathcal{B}(\varphi_1, \Phi_g \varphi_2) = 2\pi \sum_{n=-\infty}^{\infty} \int_{-\infty}^{\infty} dl^y \int_{-\infty}^{\infty} dk^y \frac{a_1^*(n, l^y, 0)}{\sqrt{\omega(n, l^y)}} \frac{a_2(n, k^y, 0)}{\sqrt{\omega(n, k^y)}}, \quad (5.16)$$

where now

$$\omega(n, k^y) = \sqrt{n^2 + k^{y2}}, \quad (5.17)$$

$$\omega(n, l^y) = \sqrt{n^2 + l^{y2}}. \quad (5.18)$$

We thus have

$$\int_G dg \mathcal{B}(\varphi_1, \Phi_g \varphi_2) = \sum_{n=-\infty}^{\infty} A_{1n}^* A_{2n}, \quad (5.19)$$

where we have defined

$$A_n = \frac{\sqrt{2\pi}}{i} \int_{-\infty}^{\infty} dk \frac{1}{(n^2 + k^2)^{1/4}} a(n, k, 0), \quad n = 0, \pm 1, \pm 2, \dots, \quad (5.20)$$

which is a rapidly decreasing sequence of complex numbers.

The null spaces of μ_G and Ω_G coincide and consist of the solutions of the massless Klein–Gordon equation in which $A_n = 0$ for all n . Taking the quotient by the null space, we see that $\hat{\mathcal{S}}$ consists of the set of rapidly decreasing complex sequences, $\mathbf{A} = \{A_n, n = 0, \pm 1, \pm 2, \dots\}$. Formula (5.20) defines the projection $\pi: \mathcal{S} \rightarrow \hat{\mathcal{S}}$. On $\hat{\mathcal{S}}$ the reduced bilinear forms are then

$$\hat{\Omega}(\mathbf{A}_1, \mathbf{A}_2) = i \sum_{n=-\infty}^{\infty} (A_{1n}^* A_{2n} - A_{1n} A_{2n}^*), \quad (5.21)$$

$$\hat{\mu}(\mathbf{A}_1, \mathbf{A}_2) = \frac{1}{2} \sum_{n=-\infty}^{\infty} (A_{1n}^* A_{2n} + A_{1n} A_{2n}^*). \quad (5.22)$$

Both of the reduced forms are nondegenerate and $\hat{\mu} > 0$. It is straightforward to check that $\hat{\mu}$ bounds $\hat{\Omega}$ and so defines a quasi-free state on $\mathcal{A}(\hat{\mathcal{S}}, \hat{\Omega})$.

The bilinear forms (5.21) and (5.22) correspond with those used to define the phase space, CCR algebra, and vacuum state in the BHP quantization of the polarized Gowdy T^3 model.^{10–12} To see this, we first recall the BHP CCR algebra and vacuum state.

The set of smooth solutions \mathcal{Q} to the reduced field equation (5.5) on \hat{M} takes the form

$$\psi(\tau, \sigma) = \frac{1}{\sqrt{4\pi}} a_0 (1 - i \ln \tau) + \frac{1}{2\sqrt{2}} \sum_{\substack{n=-\infty \\ n \neq 0}}^{\infty} a_n H_0(|n|\tau) e^{in\sigma} + \text{c.c.}, \quad (5.23)$$

where a_n $n=0, \pm 1, \pm 2, \dots$ is a rapidly decreasing sequence of complex constants. The BHP CCR algebra is defined by \mathcal{Q} and the symplectic form

$$C(\psi_1, \psi_2) = i \sum_{n=-\infty}^{\infty} (a_{1n}^* a_{2n} - a_{1n} a_{2n}^*). \quad (5.24)$$

The BHP vacuum state may be defined by the scalar product

$$D(\psi_1, \psi_2) = \frac{1}{2} \sum_{n=-\infty}^{\infty} (a_{1n}^* a_{2n} + a_{1n} a_{2n}^*), \quad (5.25)$$

although the restriction of D to the zero frequency sector (spanned by $\{a_0, a_0^*\}$) is essentially arbitrary.

Let $\mathcal{S}_0 \subset \mathcal{S}$ denote the set of massless Klein–Gordon fields that satisfy $a(0, k^y, 0) = 0$. Denote by $\hat{\mathcal{S}}_0 \subset \hat{\mathcal{S}}$ the image of \mathcal{S}_0 under the projection π . $\hat{\mathcal{S}}_0$ is the vector space of sequences $\mathbf{A}_0 = \{A_n\}$, $n = \pm 1, \pm 2, \dots$. In terms of fields on M and \hat{M} the projection, $\pi: \mathcal{S}_0 \rightarrow \hat{\mathcal{S}}_0$ is given by the group average of the scalar field (see the Appendix),

$$\pi\varphi(t, \vec{x}) = \int_G dg \Phi_g \varphi(t, \vec{x}) = \frac{1}{2\sqrt{2}} \sum_{\substack{n=-\infty \\ n \neq 0}}^{\infty} (A_n H_0(|n|\tau) e^{inx} + A_n^* H_0^*(|n|\tau) e^{-inx}), \quad (5.26)$$

where $\tau = \sqrt{t^2 - y^2}$ and H_0 is the zeroth-order Hankel function of the second kind. Indeed, with $\varphi \in \mathcal{S}_0$ we have

$$\int_G dg \Phi_g \varphi(t, \vec{x}) = 0 \Leftrightarrow \mathbf{A}_0 = 0. \quad (5.27)$$

Thus we can identify $\hat{\mathcal{S}}_0$ with the vector space of solutions $\mathcal{Q}_0 \subset \mathcal{Q}$ to the reduced field equations with vanishing zero frequency modes via $a_n = A_n$ and $a_0 = 0$. With this identification in hand, it is straightforward to verify that the restriction of $\hat{\Omega}$ and $\hat{\mu}$ to $\hat{\mathcal{S}}_0$ is precisely the restriction to \mathcal{Q}_0 of the bilinear forms C and D used to define the BHP CCR algebra and vacuum state.

The group averages of elements of \mathcal{S} do not in general exist as fields on \hat{M} ; the putative projection to the zero frequency mode does not converge (see the Appendix). (The group average of an element of \mathcal{S} can, however, be interpreted as defining a G -invariant linear functional on \mathcal{S} and hence a linear functional on $\hat{\mathcal{S}}$.) Thus, while $\hat{\mathcal{S}}$ is isomorphic to \mathcal{Q} , the isomorphism is not determined in the zero mode sector. Writing $\hat{\mathcal{S}} = \mathcal{Z} \oplus \hat{\mathcal{S}}_0$, where \mathcal{Z} is the two-dimensional symplectic space of zero frequency solutions, the most general symplectic isomorphism from $\hat{\mathcal{S}}$ to \mathcal{Q} is determined by the symplectic isomorphisms of \mathcal{Z} . Thus $\hat{\mu}$ will differ from D only by the pull back of a symplectic transformation on \mathcal{Z} .

To summarize, aside from zero mode ambiguities, the BHP vacuum state can be interpreted as arising from: (i) construction of a subalgebra $\mathcal{A}(\mathcal{S}, \Omega)$ of the CCR algebra of the massless Klein–

Gordon field by restricting the algebra to solutions with support in M ; (ii) definition of a quasi-free state ω on $\mathcal{A}(\mathcal{S}, \Omega)$ by restriction of the Poincaré invariant vacuum state to $\mathcal{A}(\mathcal{S}, \Omega)$; and (iii) symmetry reduction of $\mathcal{A}(\mathcal{S}, \Omega)$ and ω by the group G .

It is known that the GNS representation of the CCR algebra defined by the BHP vacuum state does not allow for unitary implementation of time evolution $\tau \rightarrow \tau + \text{const}$. It is now easy to see why this would be the case: the BHP vacuum state comes from symmetry reduction of the Poincaré invariant Klein–Gordon vacuum state, which defines a representation of the Klein–Gordon CCR algebra designed to unitarily implement Poincaré transformations. Evolution in τ is not a Poincaré transformation and, from the results in Ref. 17, cannot be expected to be unitarily implemented.

APPENDIX: DERIVATION OF (5.26)

Here we derive (5.26). The action of $g=(n, \alpha, \beta)$ on a field $\varphi \in \mathcal{S}$ is

$$\begin{aligned} \Phi_g \varphi(t, x, y, z) = & \int d^3k \sqrt{\frac{1}{2\omega(k)(2\pi)^3}} (a(\vec{k}) e^{2\pi i k^x n} e^{i k^z \beta} e^{i k^x x + i k^z z} \\ & \times e^{i y [k^y \cosh(\alpha) - \omega(k) \sinh(\alpha)]} e^{-i t [\omega(k) \cosh(\alpha) - k^y \sinh(\alpha)]} + \text{c.c.}), \end{aligned}$$

where $\omega(k) = \sqrt{k^x{}^2 + k^y{}^2 + k^z{}^2}$. The group average involves a sum over all $n \in \mathbf{Z}$ and integrals over $\alpha, \beta \in \mathbf{R}$. The sum over n leads to a periodic delta function in k^x while the integral over β yields a delta function in k^z . We thus get

$$\begin{aligned} \int_G dg \Phi_g \varphi(t, x, y, z) = & 2\pi \sum_{n=-\infty}^{\infty} \int_{-\infty}^{\infty} d\alpha \int_{-\infty}^{\infty} dk^y \sqrt{\frac{1}{2\omega(k^y, n)(2\pi)^3}} (a(n, k^y, 0) e^{i n x} \\ & \times e^{i y [k^y \cosh(\alpha) - \omega(k^y, n) \sinh(\alpha)]} e^{-i t [\omega(k^y, n) \cosh(\alpha) - k^y \sinh(\alpha)]} + \text{c.c.}), \end{aligned}$$

where now $\omega(k^y, n) = \sqrt{n^2 + k^y{}^2}$.

Using the coordinates $(\tau, \sigma, \eta, \xi)$ defined in (5.2) and changing variables $\alpha \rightarrow \alpha + \eta$, we have

$$\begin{aligned} \int_G dg \Phi_g \varphi(t, x, y, z) = & 2\pi \sum_{n=-\infty}^{\infty} \int_{-\infty}^{\infty} d\alpha \int_{-\infty}^{\infty} dk^y \\ & \times \sqrt{\frac{1}{2\omega(k^y, n)(2\pi)^3}} (a(n, k^y, 0) e^{i n \sigma} e^{i \tau [k^y \sinh(\alpha) - \omega(k^y, n) \cosh(\alpha)]} + \text{c.c.}). \end{aligned}$$

The $n=0$ term in the above expression is given by

$$\mathcal{I} = \int_{-\infty}^{\infty} d\alpha \int_{-\infty}^{\infty} dk^y \sqrt{\frac{1}{2|k^y|(2\pi)^3}} (a(0, k^y, 0) e^{i \tau [k^y \sinh(\alpha) - |k^y| \cosh(\alpha)]} + \text{c.c.}),$$

which does not converge for $a(\vec{k})$ in Schwarz space. Henceforth we restrict to elements of \mathcal{S} which satisfy $a(0, k^y, 0) = 0$ so that we may restrict to $n \neq 0$ in what follows.

Defining v by

$$\cosh(v) = \frac{\omega(k^y, n)}{|n|}, \quad \sinh v = -\frac{k^y}{|n|},$$

and making the change in variables $\alpha \rightarrow \alpha + v$, we have

$$\int_G dg \Phi_g \varphi = 2\pi \sum_{\substack{n=-\infty \\ n \neq 0}}^{\infty} \int_{-\infty}^{\infty} d\alpha \int dk^y \sqrt{\frac{1}{2\omega(k^y, n)(2\pi)^3}} (a(n, k^y, 0) e^{in\sigma - i|n|\tau \cosh(\alpha)} + \text{c.c.}).$$

We recall the integral representation of the zeroth-order Hankel function of the second kind,

$$H_0^{(2)}(z) = -\frac{1}{\pi i} \int_{-\infty}^{\infty} ds e^{-iz \cosh s}.$$

Thus we have

$$\begin{aligned} \int_G dg \Phi_g \varphi &= \frac{\sqrt{\pi}}{2i} \sum_{\substack{n=-\infty \\ n \neq 0}}^{\infty} \int dk \sqrt{\frac{1}{\omega(k^y, n)}} (a(n, k, 0) e^{in\sigma} H_0^{(2)}(|n|\tau) + \text{c.c.}) \\ &= \frac{1}{2\sqrt{2}} \sum_{\substack{n=-\infty \\ n \neq 0}}^{\infty} (A_n e^{in\sigma} H_0(|n|\tau) + \text{c.c.}) \end{aligned}$$

with A_n defined in (5.20).
