Special Assistant to the Director for Greenhouse Gas Measurements

- Program & Project Objectives
- What is measured
- Background about LIDAR and Differential Absorption LIDAR
- Our Approaches
- Results and Current Status

CHALLENGES FOR GHG EMISSION MEASUREMENTS

- **Develop** and **validate** advanced **measurement tools** that improve the quantitative determination of GHG sources and sinks and the accuracy of climate science measurements
- Deliverable: **Transfer** new, validated diagnostic and measurement **technologies to the private sector** and embody their methods in **documentary standards**.

Project Objectives – Diff. Absorption LIDAR

- Develop methods for accurately quantifying greenhouse gas emissions from natural and anthropogenic distributed sources and sinks.
- Develop an indoor testing facility to rigorously test hardware components and software algorithms in well quantified conditions.

SUPPORT MEASUREMENT BASED GHG INVENTORIES

GHG Flowrate (Flux)

$$\dot{m}_{\text{ghg}} = \sum \dot{m}_t x_{gi}$$

Where: \dot{m}_t is total mass flow rate

x_{gi} is relative abundance of i^{th} gas

Inventory: Sum of continuous flux over a year
(either emissions to or capture from the atmosphere)

*For a flux measurement, both the **density** of GHG **and** its **velocity** are required, along with error contributions from both quantities.*

- **Construct prototype DIAL systems for the detection of GHGs from distributed area sources**
 - 3 - 5 km range**
 - ~10 meter spatial resolution**
- **Integrate DIAL concentration measurements with measurements of wind speed (Doppler LIDAR)**
- **Develop and assess GHG flux retrieval algorithms and understand measurement uncertainties**

LIGHT DETECTION AND RANGING

- 1) Pulses of laser light scatter in the atmosphere
- 2) A telescope receives a small portion of backscattered light
- 3) A detector converts received light to electronic signals
- 4) A data system digitizes and stores the signals
- 5) Range is found from pulse time-of-flight ($150 \text{ m}/\mu\text{s}$)

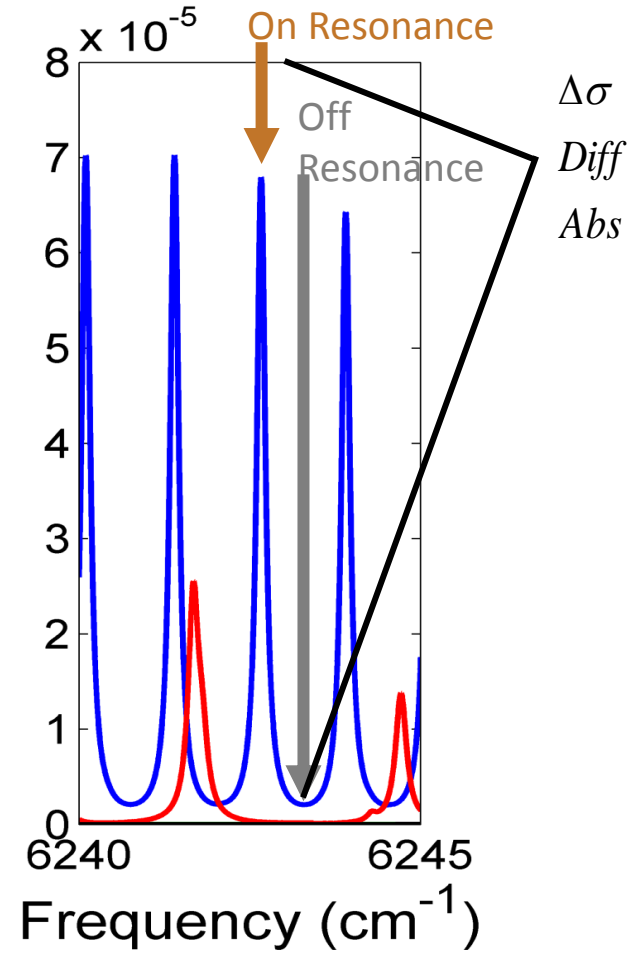

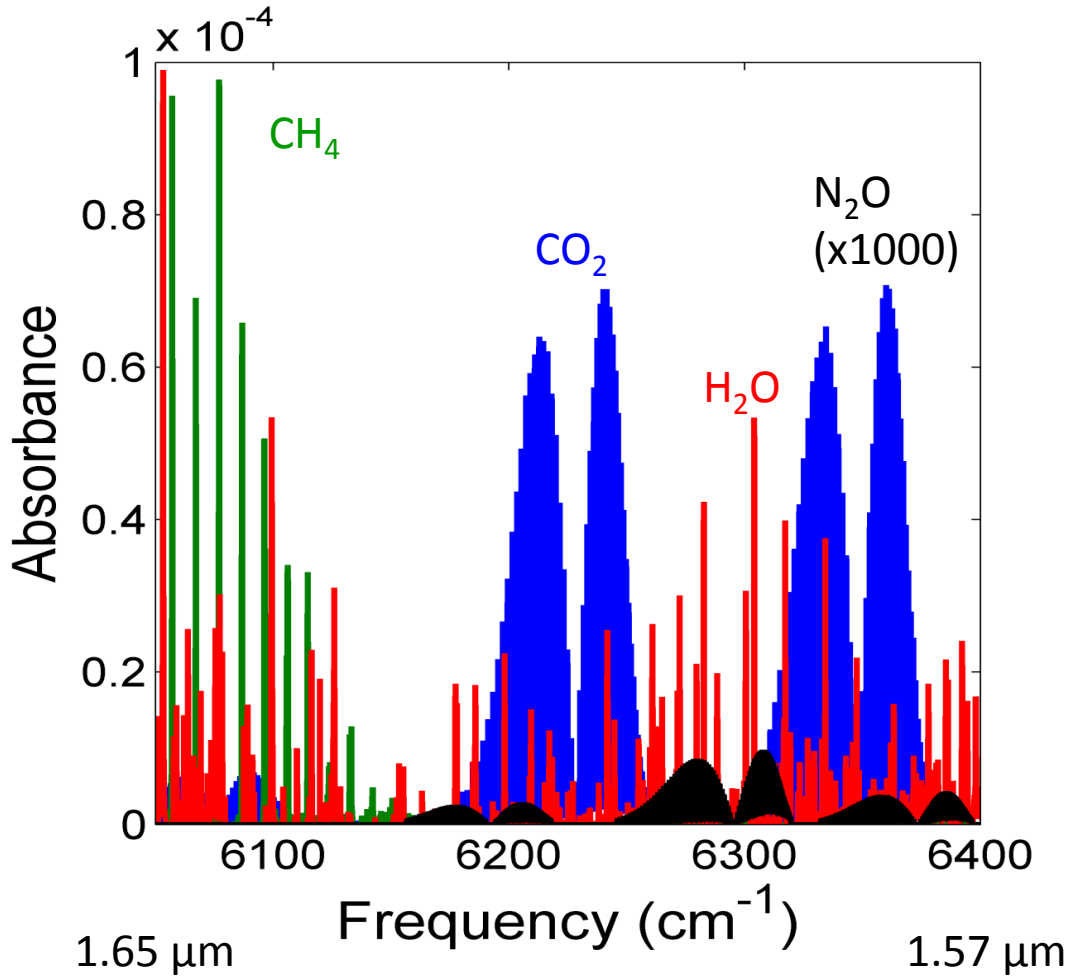

DIFFERENTIAL ABSORPTION LIDAR

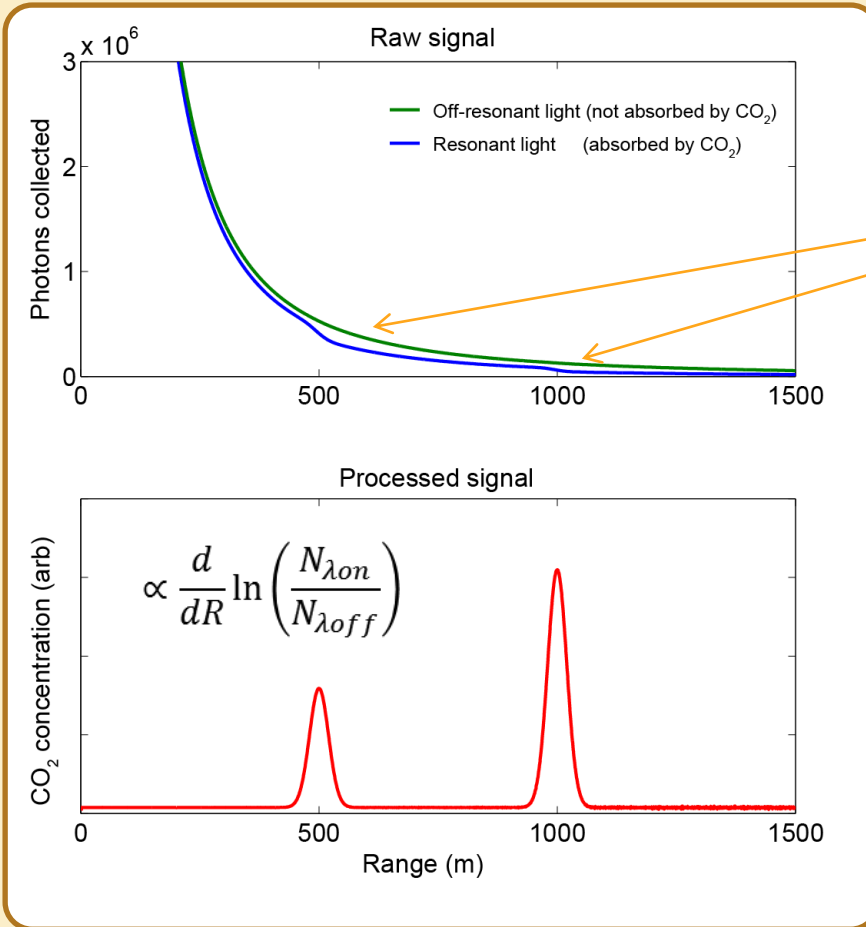

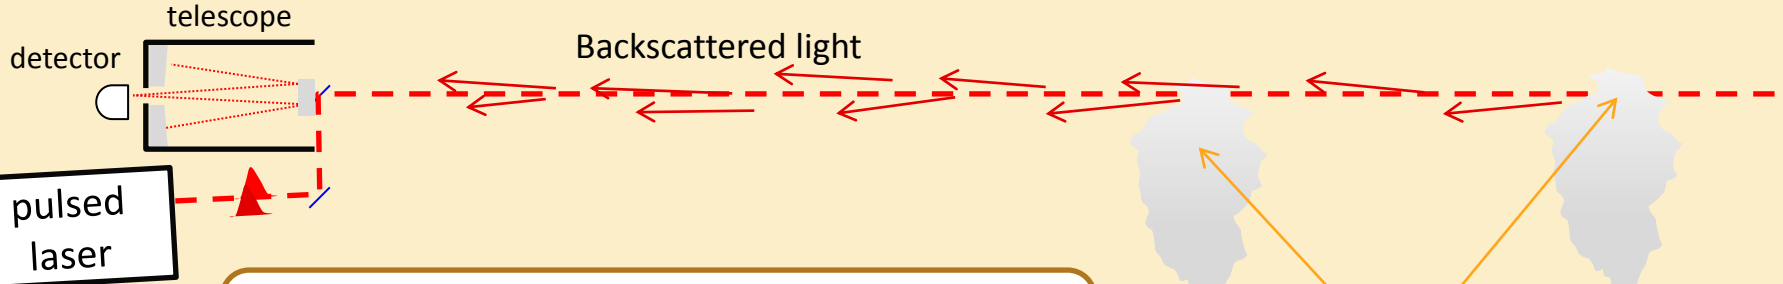

- 1) Use two or more wavelengths of light
- 2) Exploit the fact that the REFLECTANCE of atmospheric aerosols and Rayleigh backscattering are WEAKLY dependent on wavelength
- 3) Exploit the fact that the ABSORPTION of trace gases (CO_2 , CH_4 , H_2O , etc) STRONGLY depends on wavelength

- Ratio of captured reflected light at two different wavelengths as a function of time reveals the density of the measured gas as a function of distance
- Ratio removes common effects – geometry, collection efficiencies, etc.

ABSORPTION FEATURES RELEVANT FOR GHG DIAL

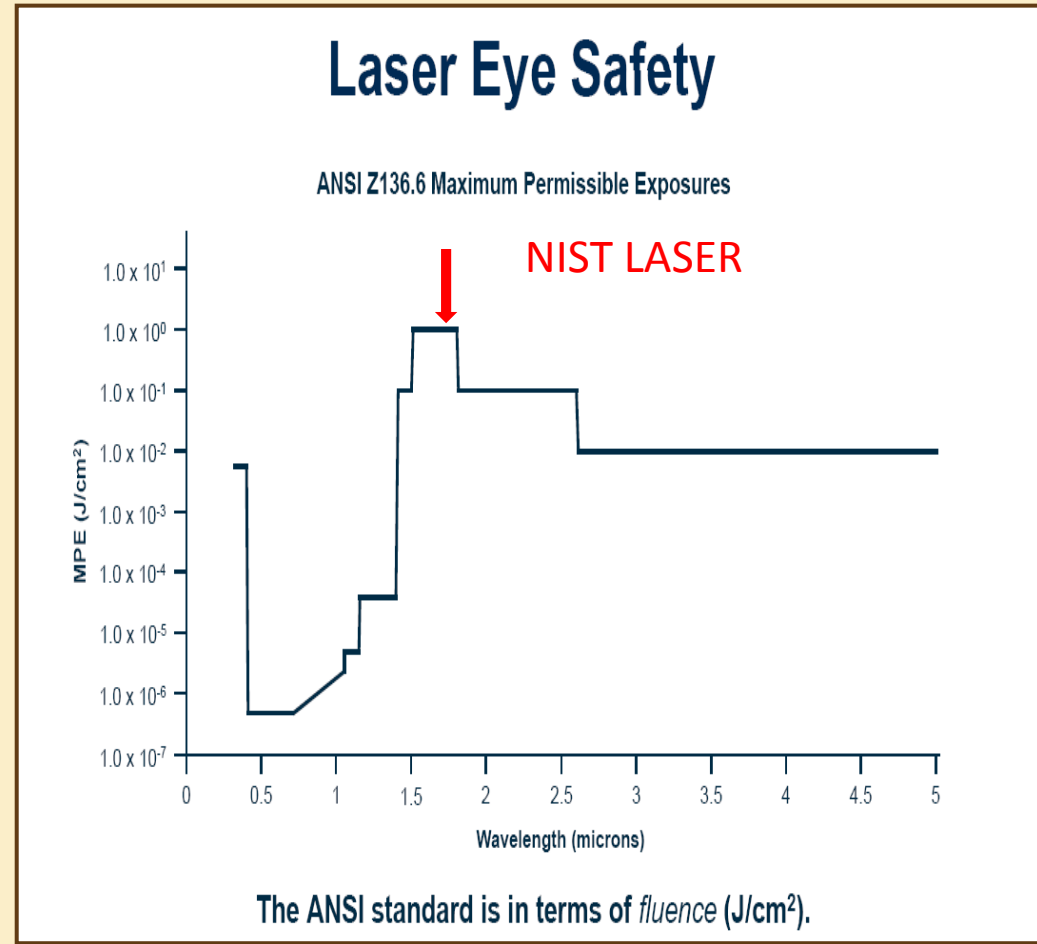

DIFFERENTIAL ABSORPTION LIDAR (DIAL) CARTOON

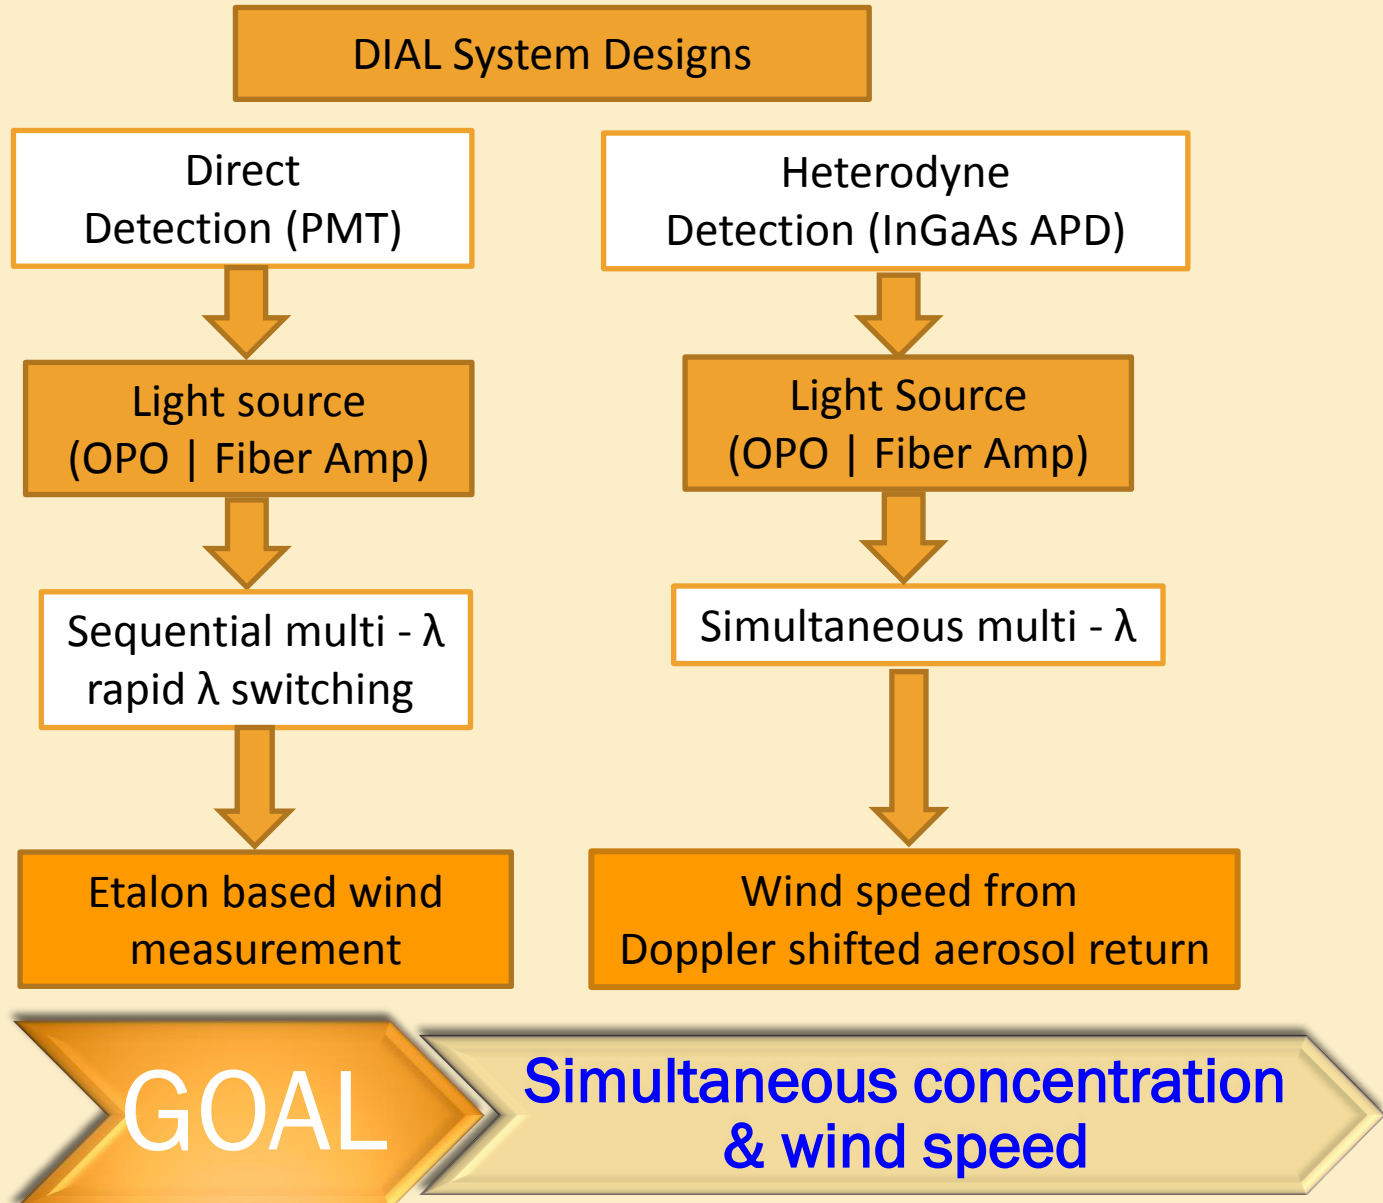

ADVANTAGES OF OPERATION IN THE NEAR IR

- Eye safety
- Wide availability of laser sources
- High sensitivity detectors (PMT)
- COTS technology from telecom industry
- Relatively weak absorption strength means DIAL can probe longer distances
- Minimal water absorption

NIST ROAD MAP TO GHG REMOTE SENSING

LIGHT SOURCE: PULSED OPO LASER SYSTEM: RISTRA

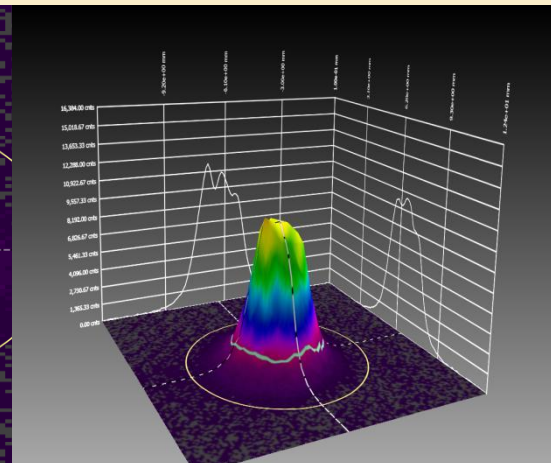

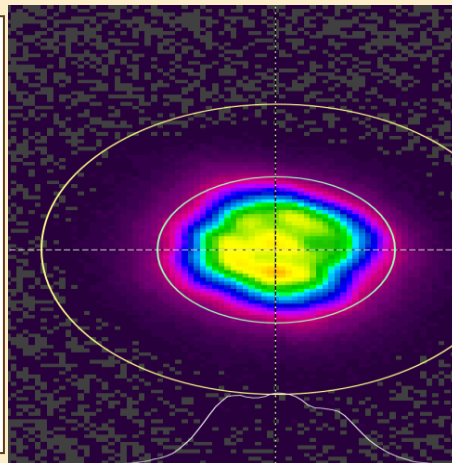

Rotated Image Singly-Resonant Twisted RectAngle

80 cm

10 cm

Demonstrated: 50 mJ/pulse at 1.6 mm
200 MHz spectral linewidth

RISTRA Optical Parametric Oscillator Features

- New technology
A tunable high energy laser source with good beam quality needed for long range remote sensing
- Wavelength ranges
Signal 1595 nm – 1650 nm
Idler 2995 nm – 3082 nm

LIGHT SOURCE: PULSED FIBER AMPLIFIER

4. OUTPUT PULSE

Input Power	500 μ W
Input Wavelength	1601nm
Booster Current	7.5A
Output Power	3.0W
Oscilloscope model	Tektronix TDS2024
Oscilloscope S#	OSC016
Pulse FWHM	200ns
ASE	6.50%

Repetition rate: 500 kHz (designed for short range)

Mean power : 3W

Peak power : 25-30W

Energy/pulse : 6 μ J

Provides a tunable high energy laser source with good beam quality needed for long range remote sensing AND ultra-portable, no alignment needed

SMALL-SCALE HARD-TARGET SYSTEM

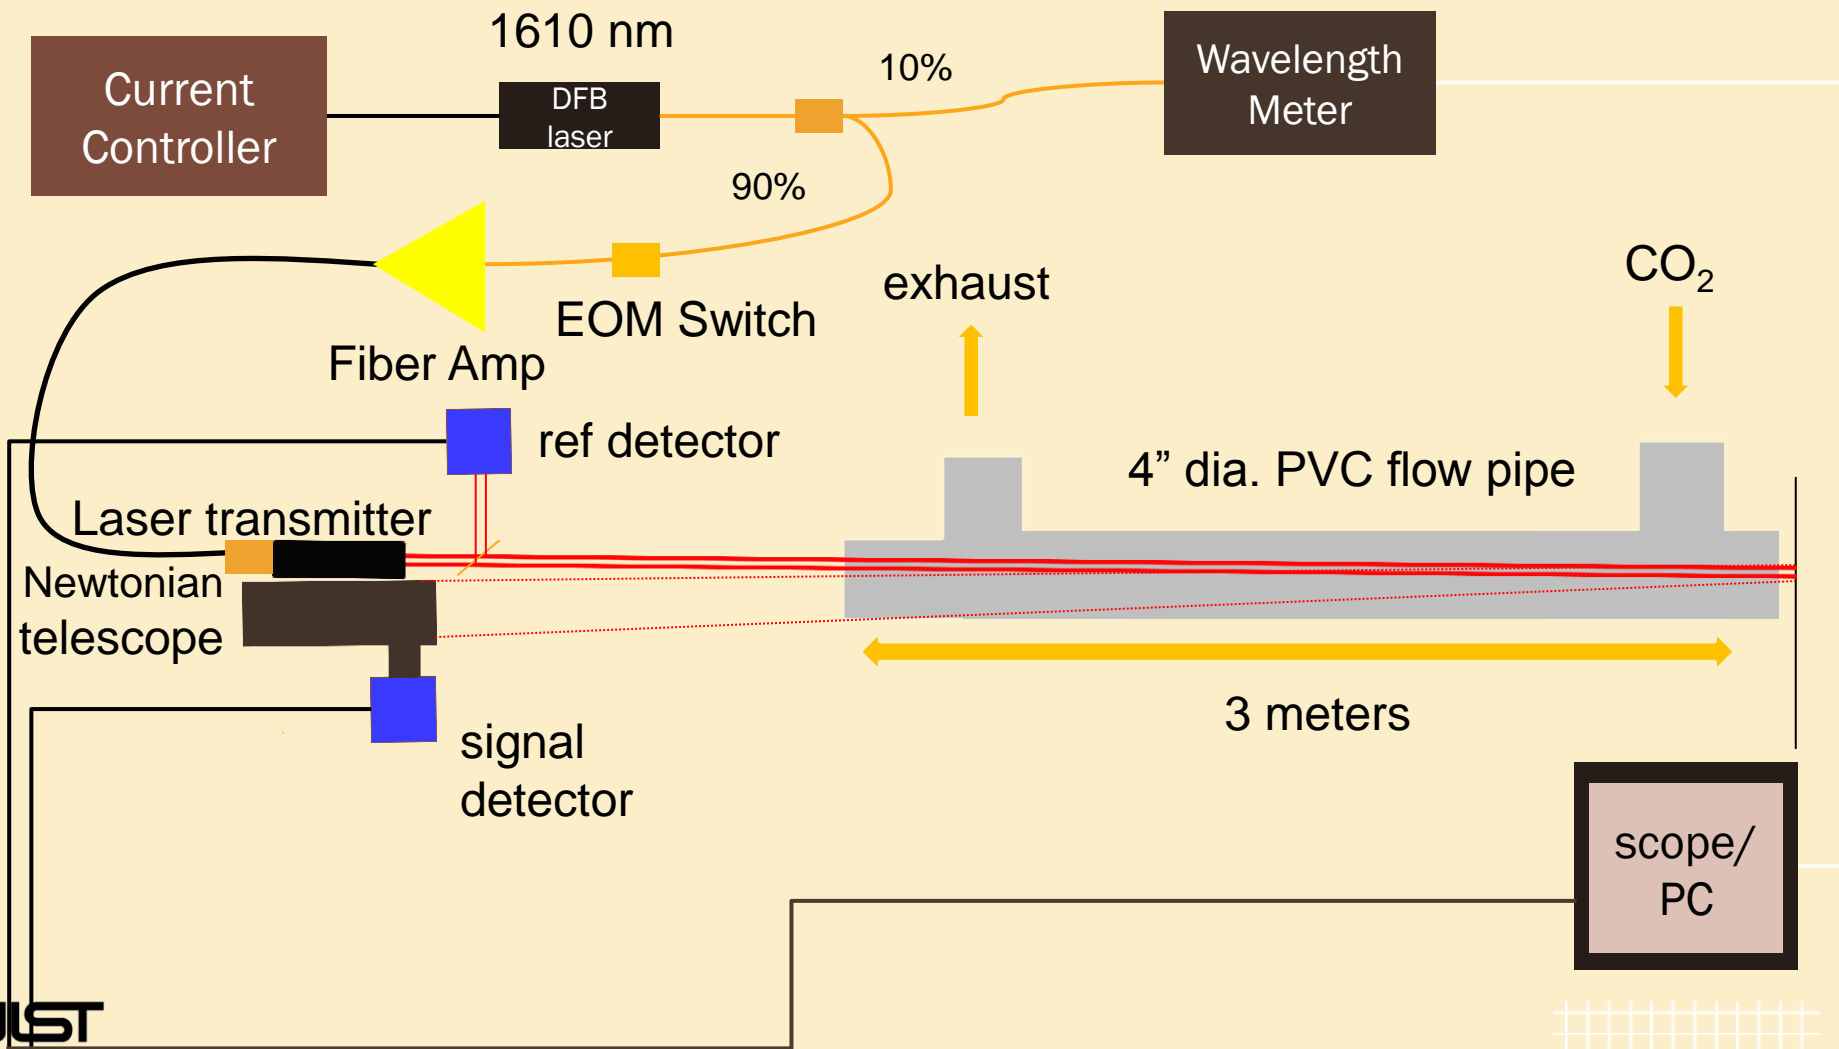

NIST

National Institute of Standards and Technology
Technology Administration, U.S. Department of Commerce

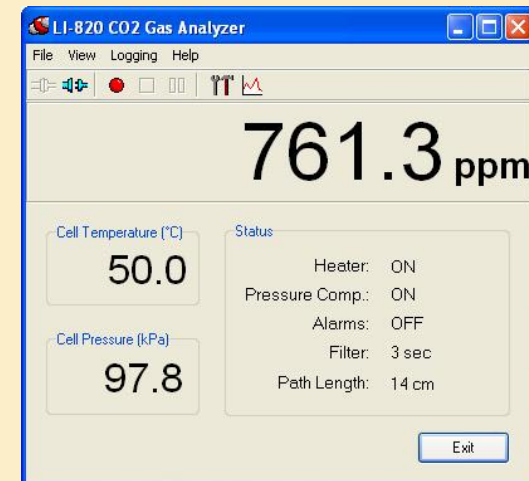

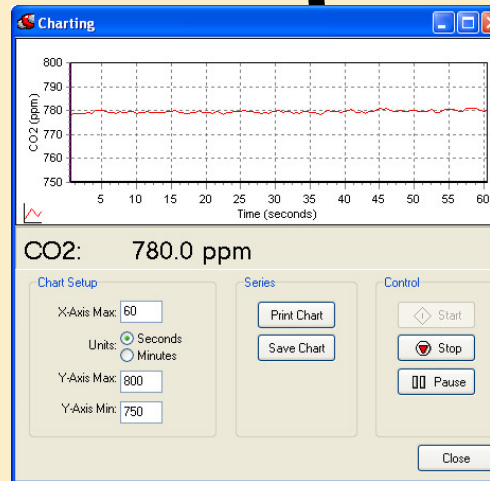

OPTICAL LAYOUT: HARD-TARGET DIAL

FLOW CELL

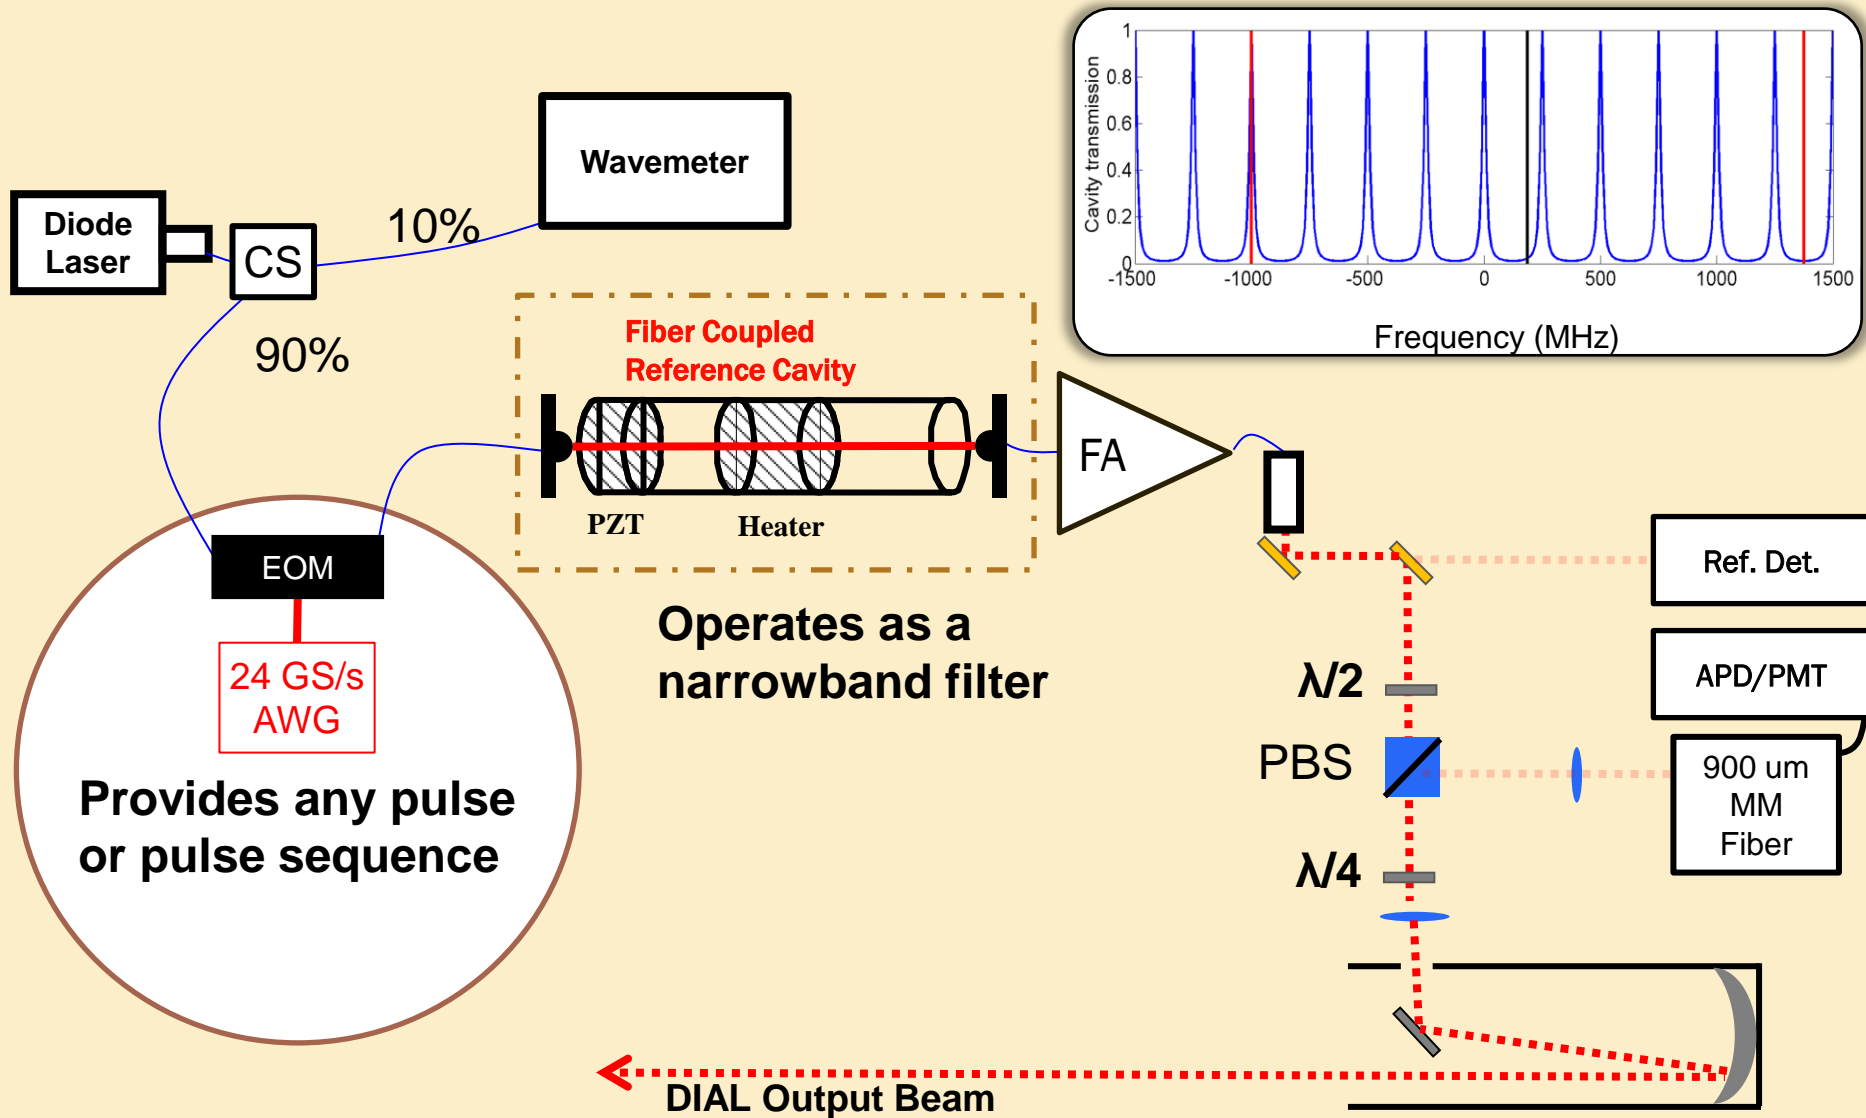

- NDIR sensor calibrated with 5500 ppm CO₂ (10% uncertainty) and zeroed with high purity N₂

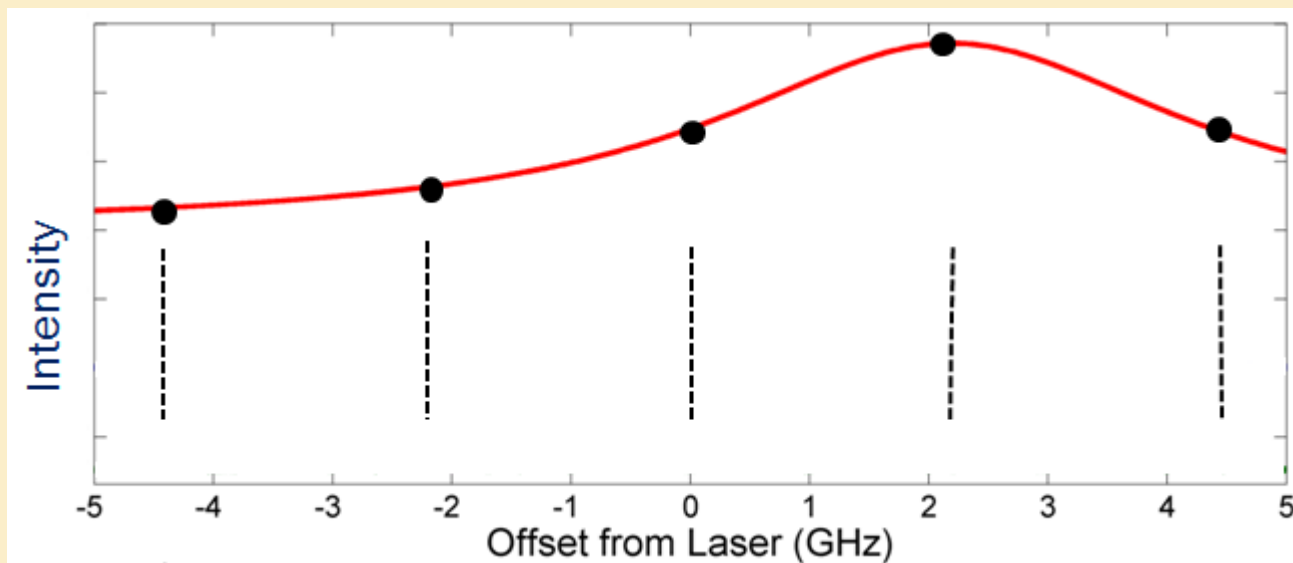

COMPARISON OF HT DIAL TO NDIR MONITOR

ETALON-BASED HIGH-SPEED WAVELENGTH SWITCHING

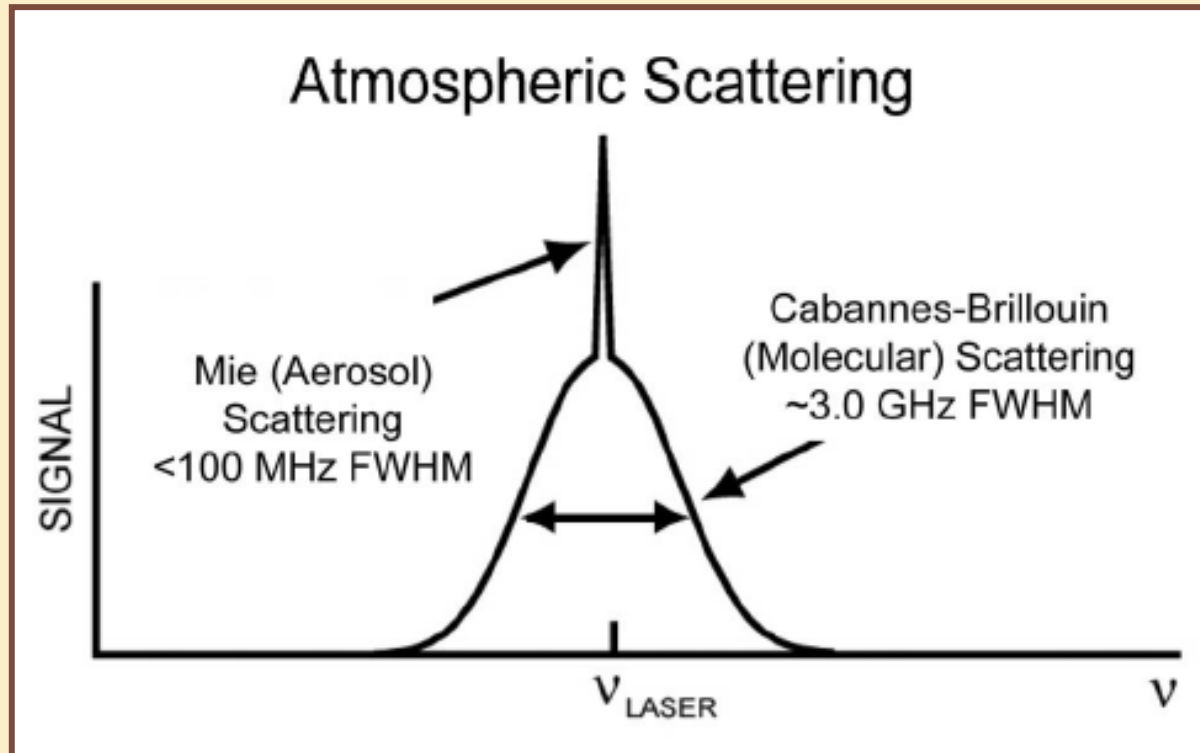

MULTI-WAVELENGTH HETERODYNE DIAL CONCEPT

— CO₂ Line Shape - HITRAN

- Produce multiple wavelengths simultaneously across the absorption line of
- Heterodyne detection puts each frequency point (black dot) on the absorption curve into a separate detection channel.

THE 2ND PARAMETER – WIND SPEED MEASUREMENT

- A 2 mph (1 m/s) wind velocity yields a 1 MHz Doppler shift at 1.6 mm
- Doppler shift can be measured using heterodyne techniques or by exploiting filter properties of Fabry-Perot cavities.

Several approaches are being pursued:

1. OPO laser system → We estimate 5 – 10 mph resolution limit
2. Fiber amplifier system → 2 mph resolution limit
3. Commercially available systems → 2 mph resolution

NIST DIAL TEST FACILITY CONFIGURATION

Flux Parameters

velocity and GHG concentration
traceable to NIST standards

DIAL
Lab

30 meter test section allows test gas
confinement for independent conc. &
velocity determination

100 meters

- Designed and constructed two prototype DIAL systems for the detection of GHGs from distributed area sources
 - OPO operating at 100 Hz
 - Fiber based amplifier operating at 500 kHz
- Developed new methods to perform rapid sequential scans for direct detection and single pulse multi-l scans for heterodyne detection.
- Developing an indoor test facility for characterization of the DIAL system in a controlled environment.
- Goal is to move system outside to characterization of GHG densities and fluxes at the few km scale
