**Abstract**

Although well publicized, measurements of Earth’s ozone layer are actually very limited. We have assembled a system to fly an ozonesonde along with other instrumentation into the stratosphere with the goal of measuring ozone to approximately 35km above sea level. We currently have a live telemetry system that relies on the sound card of the computer being used, which varies in efficiency from one computer to another. We are working on replacing that method by using a modem. The radiosonde SNR is being tested by assessing possible changes in the geometry and length of its current antenna for better transmission. Our last season’s flights data is comparable to the one provided to us by NASA HASP in October 2012. Results, current methodology being used and status of systems and antenna testing will be presented in details.

**Our method for measuring ozone concentration**

We fly a modified ECC Ozonesonde, which is designed to detect ozone molecules by utilizing a chemical cell that reacts with a dilute solution of potassium iodide to produce a weak electrical current proportional to the ozone concentration of the sampled air. We have preflight tested the system in a vacuum chamber and do system performance tests before every flight. Calibration methods are being developed.

**Ozone depletion and reconstitution process**

A single CFC molecule can destroy 100,000 ozone molecules.

\[
\text{CFC}_3 + \text{UV Light} \rightarrow \text{CFCl}_2 + \text{Cl} \\
\text{Cl} + \text{O}_3 \rightarrow \text{ClO} + \text{O}_2 \\
\text{ClO} + \text{O} \rightarrow \text{Cl} + \text{O}_2
\]

The atomic Cl is again free to destroy another ozone molecule.

**Results from 2012 season flight and tests performed in lab**
