Operation of Flaming Gorge Dam Draft Environmental Impact Statement Executive Summary
Note to the Reader

This Executive Summary provides an overview of the proposed action analyzed in the Operation of Flaming Gorge Dam Draft Environmental Impact Statement (DEIS). It is intended to provide a concise report of the proposed action, alternatives, and environmental consequences which are explained and analyzed in detail in the DEIS. Because a number of those on the DEIS mailing list asked only for a copy of this Executive Summary, it should be noted that if more information is desired, a paper or CD-ROM copy of the DEIS is available upon request; contact information is provided in the transmittal letter and in the Federal Register Notice of Availability of the DEIS. The complete DEIS and appendices are also viewable on the internet. Go to <www.usbr.gov/uc/>, click on “Environmental Programs” in the left hand column, and click on “Flaming Gorge Dam Environmental Impact Statement.” The public comment period for the DEIS ends on November 15, 2004.

Executive Summary

S.1 INTRODUCTION

The Secretary of the United States Department of the Interior (Secretary), acting through the Bureau of Reclamation (Reclamation), is considering whether to implement a proposed action under which the Flaming Gorge Dam would be operated to achieve the flow and temperature regimes recommended in the September 2000 report *Flow and Temperature Recommendations for Endangered Fishes in the Green River Downstream of Flaming Gorge Dam* (2000 Flow and Temperature Recommendations), published by the Upper Colorado River Endangered Fish Recovery Program (Recovery Program). The 2000 Flow and Temperature Recommendations specifically describe the peak flows, durations, water temperatures, and base flow criteria recommended to protect and assist in the recovery of endangered fish species.

A draft environmental impact statement (DEIS), of which this document is an executive summary, has been prepared pursuant to the National Environmental Policy Act of 1969 (NEPA), and the Council on Environmental Quality (CEQ) and Department of the Interior regulations implementing NEPA. The DEIS addresses the environmental issues associated with, and analyzes the environmental consequences of, the one action alternative determined to meet purpose and need, as well as a no action alternative.

S.2 PROPOSED FEDERAL ACTION AND BACKGROUND

Reclamation proposes to take action to protect and assist in recovery of the populations and designated critical habitat of the four endangered fishes found in the Green and Colorado River Basins (Proposed Action). The four endangered fish species are humpback chub (*Gila cypha*), Colorado...
pikeminnow (*Ptychocheilus lucius*), razorback sucker (*Xyrauchen texanus*), and bonytail (*Gila elegans*). Reclamation would implement the Proposed Action by modifying the operations of Flaming Gorge Dam, to the extent possible, to achieve the flows and temperatures prescribed in the 2000 Flow and Temperature Recommendations. Reclamation’s goal is to implement the Proposed Action and, at the same time, maintain and continue all authorized purposes of the Colorado River Storage Project (CRSP).

**S.2.1 Purpose of and Need for the Proposed Federal Action**

The purpose of the Proposed Action is to operate Flaming Gorge Dam to protect and assist in recovery of the populations and designated critical habitat of the four endangered fishes, while maintaining all authorized purposes of the Flaming Gorge Unit of the CRSP, particularly those related to the development of water resources in accordance with the Colorado River Compact. The Proposed Action is needed for the following reasons:

- The operation of Flaming Gorge Dam, under its original operating criteria, jeopardized the continued existence of the endangered fishes in the Green River.
- Reclamation is required to comply with the Endangered Species Act (ESA) for the operation of CRSP facilities, including Flaming Gorge Dam. Within the exercise of its discretionary authority, Reclamation must avoid jeopardizing the continued existence of listed species and destroying or adversely modifying designated critical habitat.
- The Reasonable and Prudent Alternative (RPA) to the 1992 Biological Opinion on the Operation of Flaming Gorge Dam required modification of Flaming Gorge releases to benefit the endangered fish, a 5-year study period to evaluate winter and spring flows, and reinitiation of discussions with the U.S. Fish and Wildlife Service following the study period to further refine the flow recommendations. With the results of these studies, as well as other relevant information, the Recovery Program developed and approved the 2000 Flow and Temperature Recommendations for the Green River. These recommendations are an extension of the 1992 jeopardy Biological Opinion RPA. Reclamation committed to assist in meeting flow requirements through the refined operation of Flaming Gorge and other federal reservoirs in the 1987 agreement that formed the Recovery Program.
- Flaming Gorge Dam and Reservoir is the primary water storage and delivery facility on the Green River, upstream from its confluence with the Colorado River. The storage capacity and ability to control water releases of Flaming Gorge Dam allow Reclamation flexibility in providing flow and temperature management, to protect and assist in the recovery of endangered fish populations and their critical habitat within specific reaches of the river. Thus, the refined operation of Flaming Gorge Dam is a key element of the Recovery Program.
- The refined operation will offset the adverse effects of flow depletions from the Green River for certain Reclamation water projects in Utah, as defined by existing jeopardy Biological Opinions. Modifying the operation of Flaming Gorge Dam will also serve as the RPA, as defined by the ESA, to offset jeopardy to endangered fishes and their critical habitat that could result from the operation of numerous other existing or proposed water development projects in the Upper Colorado River Basin.
S.3 BACKGROUND

Flaming Gorge Dam, located on the Green River in northeastern Utah about 200 miles northeast of Salt Lake City, is an authorized storage unit of the CRSP. Flaming Gorge Dam was completed in 1962, and full operation of the dam and reservoir began in 1967. The powerplant, located at the base of the dam, began commercial operation in 1963 and was completed in 1964. Reclamation operates the dam and powerplant, and Western markets the power.

S.3.1 Brief History of Flaming Gorge Dam and Reservoir

S.3.1.1 Authorized Uses of Flaming Gorge Dam and Reservoir: Colorado River Development

Flaming Gorge Dam was authorized for construction by the CRSP Act of 1956 (Public Law [P.L.] 84-485). The underlying project purposes are defined by Section 1 of the Act (43 United States Code [U.S.C.] Section (§) 620) that authorized the Secretary of the Interior to “construct, operate, and maintain” Flaming Gorge Dam:

...for the purposes, among others, of regulating the flow of the Colorado River, storing water for beneficial consumptive use, making it possible for the States of the Upper Basin to utilize, consistently with the provisions of the Colorado River Compact, the apportionments made to and among them in the Colorado River Compact and the Upper Colorado River Basin Compact, respectively, providing for the reclamation of arid and semiarid land, for the control of floods, and for the generation of hydroelectric power, as an incident of the foregoing purposes . . .

While an incident of the other listed project purposes, power generation finances the majority of both project repayment and the irrigation component of participating projects. Section 7 of the CRSP Act of 1956 mandates the operation of CRSP powerplants to produce “...the greatest practicable amount of power and energy that can be sold at firm power and energy rates . . .” However, as described in the DEIS in section 1.4.4, continued Upper Basin development of water resources is dependent on the success of the endangered fish recovery efforts, which in turn, may affect the practicable amount of power and energy generated. This Executive Summary analyzes these effects.

In 1968, Congress enacted the Colorado River Basin Project Act (43 U.S.C. § 1501 et seq.) which provided for a program for further comprehensive development of Colorado River Basin water resources. Section 1501(a) states:

This program is declared to be for the purposes, among others, of regulating the flow of the Colorado River; controlling floods; improving navigation; providing for the storage and delivery of the waters of the Colorado River for reclamation of lands, including supplemental water supplies, and for municipal, industrial, and other beneficial purposes; improving water quality; providing for basic public outdoor recreation facilities; improving conditions for fish and wildlife; and the generation and sale of electrical power as an incident of the foregoing purposes.
In addition, the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs (including Flaming Gorge Reservoir) were mandated by Section 602(a) of the 1968 Colorado River Basin Project Act. Article I.(2) of the criteria requires that the Annual Operating Plan for Colorado River reservoirs “... shall reflect appropriate consideration of the uses of the reservoirs for all purposes, including flood control, river regulation, beneficial consumptive uses, power production, water quality control, recreation, enhancement of fish and wildlife, and other environmental factors.”

S.3.1.2 Authorized Uses of Flaming Gorge Dam and Reservoir: Flaming Gorge National Recreation Area

The Flaming Gorge National Recreation Area was established by the Flaming Gorge National Recreation Area Act of 1968 (P.L. 90-540). According to that act, the purposes of the Flaming Gorge National Recreation Area are to provide (1) public outdoor recreation benefits; (2) conservation of scenic, scientific, historic, and other values contributing to enjoyment, and (3) such management, utilization, and disposal of natural resources that will promote or are compatible with and do not significantly impair the purposes for which the recreation area was established. The act added about 123,000 acres to Ashley National Forest and assigned management of the entire recreation area to the USDA Forest Service. The Flaming Gorge National Recreation Area contains 207,363 acres of land and water that are almost equally divided between Utah and Wyoming.

S.4 OPERATIONAL MODIFICATIONS SINCE THE BEGINNING OF DAM OPERATIONS

Construction of Flaming Gorge Dam and Powerplant began in 1956. Filling of the reservoir began in 1962 when the dam was completed. Full operation began in November 1967. Until 1984, Flaming Gorge Dam was operated to provide for a full reservoir while maximizing power generation, providing associated ancillary services, and avoiding the use of the river outlet works or the spillway. From 1967 until 1984, flows fluctuated as needed to meet system power demand, with consideration given to known fish and wildlife needs.

The history of Flaming Gorge Dam operations can be divided into five phases. During the first phase, from 1962 to 1966, the reservoir was filling with water, and Green River flows downstream of the dam were reduced. The first full year of normal operations began in 1967. During the second phase, from 1967 to 1978, Flaming Gorge Dam was operated with few constraints, and water releases were made through the powerplant. The only constraint on releases during phase two was in 1974 when a 400-cubic-foot-per-second (cfs) minimum release was implemented to establish and maintain the tailwater trout fishery (1974 Interim Operating Criteria). This operating agreement between the Utah Division of Wildlife Resources and Reclamation stated:

A minimum flow of 400 cfs will be released from the reservoir at all times. However, for the foreseeable future and under normal conditions, a continuous flow of 800 cfs will be maintained as a minimum. To the extent the available water supply will permit and is compatible with multipurpose operations of all CRSP reservoirs, minimum flows in excess of 800 cfs will be maintained to enhance the use of the river for fishing, fish spawning, and boating.
In 1978, the dam was retrofitted with a selective withdrawal structure to improve water temperatures for the tailwater trout fishery. During the third phase, from 1979 to 1984, operations were similar to those in the previous phase except for use of the selective withdrawal structure and the occurrence of spills in 1983 and 1984.

During the fourth phase, from 1985 to 1992, Reclamation began to constrain the operation of Flaming Gorge Dam to reduce negative impacts affecting endangered fishes in the Green River. Such constraints reduced operational flexibility and the ability to fluctuate flows to meet power system demands. In 1985, an interim flow agreement was established between Reclamation and the U.S. Fish and Wildlife Service to change Flaming Gorge Dam releases to protect critical nursery habitats for endangered fishes in the Green River downstream from Jensen, Utah. The recommended releases were based on observations made in 1985 that indicated "good" habitat conditions were available at lower flows. Reclamation also revised operational criteria at the dam to avoid spills. These changes were in place in the fourth phase, along with numerous research releases to support preparation of the Final Biological Opinion on the Operation of Flaming Gorge Dam issued on November 25, 1992. Significant financial impacts to hydropower generation, identified in the DEIS, occurred mainly as a result of flow changes implemented during this fourth phase.

In the fifth phase, from 1993 to present, Reclamation began making releases from Flaming Gorge Dam in an attempt to meet the flow and temperature recommendations given in the 1992 Biological Opinion. Flows recommended in the 1992 Biological Opinion were intended to restore a more natural hydrograph and protect nursery habitats of endangered fishes downstream from the Yampa River confluence. At the same time, Reclamation continued to meet the authorized purposes of Flaming Gorge Dam—regulating flows of the Green River, storing water, facilitating States’ development of water resources, providing recreational opportunities, generating hydroelectric power, and improving conditions for fish and wildlife.

The Green River flows recommended in the 1992 Biological Opinion were based on the most reliable scientific data available at the time. The opinion included several actions Reclamation could take to avoid jeopardizing the recovery of endangered fishes in the Green River. One of these actions was to collect more information about the flow and temperature needs of the endangered fishes and, subsequently, to refine or modify the flow and temperature recommendations of the 1992 Biological Opinion. A 5-year research study began in 1992, and the resulting data and refinements were included in the 2000 Flow and Temperature Recommendations. The study included periodic test flows to evaluate the effects of summer flows on endangered fishes or to test specific hypotheses.

S.5 COMPLIANCE WITH THE ENDANGERED SPECIES ACT

To comply with the ESA, an evaluation of the effects of any discretionary Federal action must be conducted by the action agency in consultation with the U.S. Fish and Wildlife Service.

During the late 1970s and early 1980s, the U.S. Fish and Wildlife Service rendered Jeopardy Biological Opinions for the Upalco, Jensen, and Uinta Units of the Central Utah Project stating that all relied on the operation of Flaming Gorge Dam to provide flows for endangered fishes. More recent Biological Opinions for the Duchesne River Basin,
Narrows Project, Price-San Rafael Salinity Control Project, and other water development-related projects in the Colorado River Basin also rely on the operation of Flaming Gorge Dam to provide flows for endangered fishes.

On February 27, 1980, the U.S. Fish and Wildlife Service requested consultation under Section 7 of the ESA for projects currently under construction in the Upper Colorado River Basin, and for the continued operation of all existing Reclamation projects in the basin (including the CRSP). Formal consultation on the operation of Flaming Gorge Dam began March 27, 1980. Issuance of a Final Biological Opinion by the U.S. Fish and Wildlife Service for the operation of Flaming Gorge Dam was delayed until data collection and studies related to habitat requirements for the endangered fishes could be completed and used to recommend specific flows in the Green River downstream from the dam. Dam operations were initially evaluated for potential effects on endangered fishes from 1979 to 1984. Reclamation served as the lead agency for this consultation, with Western becoming a party to the consultation in 1991.

Additionally, on February 27, 1980, the U.S. Fish and Wildlife Service issued a Final Biological Opinion for the Strawberry Aqueduct and Collection System, a major feature of the Central Utah Project. The Biological Opinion determined that Strawberry Aqueduct and Collection System flow depletions from the Duchesne and Green Rivers would likely jeopardize the continued existence of the endangered Colorado pikeminnow and humpback chub. This Biological Opinion included a Reasonable and Prudent Alternative stating that Flaming Gorge Dam and Reservoir would compensate for those depletions and be operated for the benefit of the endangered fishes in conjunction with its other authorized purposes.

Both the 1992 Biological Opinion and the 2000 Flow and Temperature Recommendations were designed to account for the impacts of depletions mentioned above. The 2000 Flow and Temperature Recommendations as implemented under the Action Alternative would offset the impacts of water depletions on these other projects.

S.5.1 Upper Colorado River Endangered Fish Recovery Program

The Recovery Program was initiated in 1987 as a cooperative effort among the States of Utah, Colorado, and Wyoming; environmental and water user organizations; Federal agencies including the National Park Service, Reclamation, U.S. Fish and Wildlife Service, and Western; and the Colorado River Energy Distributors Association. The goal of the Recovery Program is to protect and recover the endangered fish species of the Upper Colorado River Basin so they no longer need protection under the ESA, while the Upper Basin States continue to develop their 1922 Colorado River Compact entitlements.

Under the Recovery Program, five key elements are needed to recover the endangered fish species: (1) habitat management; (2) habitat development/maintenance; (3) native fish stocking; (4) nonnative species and sport fish management; and (5) research, data management, and monitoring. The operation of Flaming Gorge Dam is essential to successful implementation of two of these five elements: habitat management and habitat development/maintenance. Operation of the dam is one of many management actions described in the 1993 Recovery Implementation Program Recovery Action Plan (Recovery Action Plan). The plan is periodically revised to accommodate programmatic
Biological Opinions and annual updates as well as the designation of critical habitat for the endangered fishes. Implementation of all Recovery Action Plan recommendations is expected to achieve recovery of the endangered fishes.

S.5.2 Final Biological Opinion on the Operation of Flaming Gorge Dam and the Reasonable and Prudent Alternative

The U.S. Fish and Wildlife Service issued a Final Biological Opinion on the Operation of Flaming Gorge Dam on November 25, 1992, stating that the current operation of Flaming Gorge Dam was likely to jeopardize the continued existence of the endangered fishes in the Green River. The opinion also described elements of an RPA that, in the opinion of the U.S. Fish and Wildlife Service, would offset jeopardy to the endangered fishes. The RPA required implementing the following five elements:

1. Refining the operation of Flaming Gorge Dam so flow and temperature regimes of the Green River more closely resemble a natural hydrograph.

2. Conducting a 5-year research program, including implementation of winter and spring research flows, beginning in 1992, to allow for potential refinement of flows for those seasons. The research program was to be based on the Flaming Gorge Flow Recommendations Investigation and called for annual meetings to refine seasonal flows consistent with research findings and water year forecasts. Except for specific research flows during the 5-year research program, year-round flows in the Green River were to resemble a natural hydrograph described under element 1 of the RPA.

3. Determining the feasibility and effects of releasing warmer water during the late spring/summer and investigating the feasibility of retrofitting the river bypass tubes to include power generation, thereby facilitating increased spring releases.

4. Legally protecting Green River flows from Flaming Gorge Dam to Lake Powell.

5. Initiating discussions with the U.S. Fish and Wildlife Service, after conclusion of the 5-year research program, to examine further refinement of flows for the specified endangered Colorado River fishes.

S.5.3 2000 Flow and Temperature Recommendations

The research program called for in the 1992 Biological Opinion concluded in 1996. At that time, the Recovery Program funded a synthesis of research and development of flow and temperature recommendations for the Green River. The final synthesis report contained the 2000 Flow and Temperature Recommendations, which provide the basis for Reclamation's Action Alternative analyzed in the DEIS and for additional Section 7 consultation by Reclamation and Western with the U.S. Fish and Wildlife Service.
S.6 OPERATIONAL DECISIONMAKING PROCESS AT FLAMING GORGE DAM

The process of developing an operational plan for Flaming Gorge Dam takes into consideration all resources associated with Flaming Gorge Dam identified by the Flaming Gorge Working Group. The Flaming Gorge Working Group was formed in 1993 to provide interested parties with an open forum to express their views and interests in the operation of Flaming Gorge Dam. Among others, these interests include power marketing, sport fisheries, endangered species, white water rafting, farming, land ownership, reservoir recreation, national park resources, land management, and wildlife refuge management.

The Flaming Gorge Working Group generally meets twice a year (April and August/September). These meetings are open to the public, and participants are encouraged to comment. Operational decisions are not made during the Flaming Gorge Working Group meetings; rather, these meetings are a forum for information exchange about past, current, and proposed operations at Flaming Gorge Dam. They also serve as a forum through which stakeholders can share information about specific resources of interest and the relationship between the operation of Flaming Gorge Dam and these resources. The Flaming Gorge Working Group provides input to Reclamation as well as educating various constituencies on operations at Flaming Gorge Dam.

Reclamation has sole responsibility for operations at Flaming Gorge, although the needs and expectations of stakeholders are considered in operational planning. Reclamation’s priorities are first, dam safety and, second, meeting project purposes in compliance with ESA. When conflicts in operations arise, Reclamation’s approach to conflict resolution and decisionmaking includes accepting input from all stakeholders and formulating a strategy that meets the most needs possible consistent with these established priorities.

Operational decisions for Flaming Gorge Dam are made through the Colorado River Annual Operating Plan process. A document, called the 24-Month Study, is produced monthly and contains planned monthly releases from all CRSP reservoirs. In the 24-month study, reservoir inflows are revised to reflect forecasted inflow from the National Weather Service. These forecasted inflows are input into the 24-Month Planning Model. Planned releases from Flaming Gorge are adjusted monthly to reflect changing hydrology, to meet the requirements of the ESA, and to meet CRSP authorized purposes.

Operational details and changes are coordinated as necessary with other agencies including Western, the U.S. Fish and Wildlife Service, and the Utah Division of Wildlife Resources. Generally, a variety of requests for short-term, temporary modifications in operations are often received and such requests are accommodated if they are reasonable, necessary, and do not interfere with dam safety, other authorized project purposes, or operations for ESA compliance.
S.7  EMERGENCY POWERPLANT OPERATIONS

Normal dam and powerplant operations under the Action Alternative or any other alternative could be altered temporarily to respond to emergencies. These emergencies may be associated with dam safety, power system conditions, or personal safety of individuals or groups associated with recreation or other activities on the river. The North American Electrical Reliability Council and the Western Electricity Coordinating Council have established guidelines and requirements for emergency operations of interconnected power systems that apply to Flaming Gorge Dam operations. Examples of system emergencies include insufficient generation capacity, transmission overload and voltage control, and load shedding.

S.8  PUBLIC SCOPING PROCESS FOR THE ENVIRONMENTAL IMPACT STATEMENT

The scoping process for the DEIS was initiated on June 6, 2000, with the publication in the Federal Register of a Notice of Intent to prepare an EIS. During the public scoping period, Reclamation received both written and oral comments (oral comments were received at five public scoping meetings in Utah, Colorado, and Wyoming) which were considered in determining the scope of the DEIS. The formal scoping period ended on September 5, 2000.

S.9  SCOPE OF ANALYSIS FOR THE ENVIRONMENTAL IMPACT STATEMENT

The purpose of the DEIS is to identify and consider the impacts of developing and implementing dam operations guidelines that result in protecting and assisting in the recovery of the populations and designated critical habitat of the four endangered fishes living in the Green River downstream from Flaming Gorge Dam. The scope of analysis for the DEIS focuses on responding to the following question:

If Reclamation operates Flaming Gorge Dam to achieve the 2000 Flow and Temperature Recommendations needed to avoid jeopardy and to protect and assist in the recovery of the endangered fishes and their critical habitat in the Green River, consistent with CRSP purposes, then the effect(s) on other relevant resources/issues, both upstream and downstream from the dam, would be . . .

The geographic project area, as shown in the frontispiece maps, analyzed for possible impacts of the Proposed Action and alternatives includes Flaming Gorge Reservoir and the Green River downstream from Flaming Gorge Dam, to its confluence with the Colorado River. Because the Proposed Action depends exclusively on the operation of Flaming Gorge Dam, which is dependent on inflow into the Flaming Gorge Reservoir, the Green River upstream of the reservoir is not affected.
S.10 RELATED AND ONGOING ACTIONS

This section describes laws and projects that affect the operation of Flaming Gorge Dam and may affect the potential impacts of the Proposed Action. Where applicable, these laws and projects are factored into the analysis of potential impacts under both alternatives, particularly in the Cumulative Impacts analysis of the DEIS.

S.10.1 Regulatory Requirements

Federal statutes establish a number of responsibilities for the Secretary of the Interior. These legislated responsibilities relate to the management of numerous agencies, projects, and lands, all or some relating to the operation of Flaming Gorge Dam. In some cases, the statutes specifically require the Secretary of the Interior to mandate responsibility for management of reservoirs; while in others, the statutes allow the Secretary of the Interior to grant discretionary authority.

S.10.1.1 The Law of the River

As a tributary of the Colorado River, the Green River is managed and operated according to a collection of over 50 compacts, Federal and State laws, court decisions and decrees, contracts, treaties, and regulatory guidelines collectively known as the Law of the River. This collection of documents apportions the water among the seven Basin States and Mexico, and regulates and manages riverflows. Some of the statutes included within the Law of the River having a major impact on dam operations include the Colorado River Compact of 1922, the Upper Colorado River Basin Compact of 1948, the Colorado River Storage Project Act of 1956, which authorized a comprehensive water development plan for the Upper Basin that included the construction of Flaming Gorge Dam, and the Colorado River Basin Project Act of 1968.

S.10.1.2 National Parks and Recreation Areas

The affected environment for the DEIS includes portions of Flaming Gorge National Recreation Area, Dinosaur National Monument, and Canyonlands National Park. Enabling legislation for these units includes:

- Flaming Gorge National Recreation Area Act of 1968 (P.L. 90-540)
- Antiquities Act of 1906, 16 U.S.C. 431-433. The Dinosaur National Monument was originally designated by President Wilson in October 1915 and was enlarged by President Roosevelt in 1938.

Management authorities include:

- National Park Service Organic Act (16 U.S.C. 1-4, 22, 43)
- Redwood National Park Act of 1978 (P.L. 95-250, 92 Statute 163, as amended)
S.10.1.3 Environmental Compliance

Laws and Executive orders that were designed to restore and protect the natural environment of the United States relating to air, water, land, and fish and wildlife include the following:

- Wild and Scenic Rivers Act of 1968 (16 U.S.C. 1271 et seq.)
- Clean Air Act (42 U.S.C. 7401 et seq.)
- Clean Water Act of 1972 (33 U.S.C. 1251 et seq.)
- Executive Order 11988, Floodplain Management, 1977
- Executive Order 13112, Invasive Species, 1999
- Executive Order 11990, Protection of Wetlands, 1977

S.10.1.4 Cultural Resource Laws

Laws designed to protect and preserve historic and cultural resources under Federal control include the following:

S.10.1.5 Native American Laws

Laws and policies relating to Native American consultation include the following:

- Enhancing the Intergovernmental Partnership, Executive Order 12875 of October 26, 1993 [58 Federal Register (FR) 58093]
- Consultation and Coordination with Indian Tribal Governments, Executive Order 13084 of May 14, 1998
- Protection of Indian Sacred Sites, Executive Order 13007 of May 24, 1996 [61 FR 26771]
S.10.2 Related Programs, Projects, and Activities

S.10.2.1 Recovery Program

As discussed in section S.4.1 above, the Recovery Program’s goal is to protect and recover the endangered fish of the Upper Colorado River Basin. The Recovery Program has a variety of programs and projects underway, concerning habitat acquisition or enhancement, levee removal, nonnative fish control, and native fish stocking, aimed at achieving that goal. The Proposed Action for which the DEIS has been prepared—operating Flaming Gorge Dam as specified in the Recovery Program’s 2000 Flow and Temperature Recommendations—would complement the other Recovery Program activities in moving toward endangered fish recovery.

S.10.2.2 Interim Surplus Guidelines and Colorado River Basin Project Act 602(a) Storage Requirement

Flaming Gorge is part of the Colorado Basin and is indirectly affected by decisions made under the December 2000 Colorado River Interim Surplus Guidelines Final Environmental Impact Statement. However, the effects are not measurable. In addition, Reclamation is currently preparing an environmental assessment on a proposed guideline to be used to determine the amount of Upper Basin water required under Section 602(a) of the Colorado River Basin Project Act. This guideline could affect operations at Lake Powell but most likely would not influence operations at Flaming Gorge.

S.10.2.3 Relocation of Little Hole National Recreation Trail

The 7.2-mile segment of the Little Hole National Recreation Trail along the Green River between the Flaming Gorge Dam Spillway Recreation Complex (boat ramp launching and parking area) and Little Hole Recreation Complex (boat ramps, parking, and day use areas) will be relocated by the USDA Forest Service pending funding to prevent reoccurring trail damage and loss that has occurred from past high flows. Without relocation of the trail, further damage would be expected to occur under both the No Action Alternative and the Action Alternative.

This 7.2-mile trail segment provides access to the Green River for tens of thousands of annual visitors who participate in shore and boat fishing, scenic and recreational floating, hiking, and sightseeing activities. Several commercial operators also use the trail as part of their outfitting and guiding business. Annual trail use has ranged from 54,000 to 101,000 visitors over the past 11 years. Annual visitation numbers, types, and the economic value of uses along the trail are discussed and displayed in the DEIS.

The USDA Forest Service completed a field assessment and report in July 2001 of trail locations along the 7.2-mile trail segment. This assessment identified trail damage and repairs that have occurred from 1979 to the present due to releases from the dam, either in response to extremely wet hydrologic years or to support endangered fish research studies. The assessment also addressed alternative trail designs, locations, and costs that would prevent recurring trail damage and loss. Depending on alternative trail locations, the design and construction costs ranged from $135,000 to $308,000. The USDA Forest Service will evaluate and analyze the alternative trail designs and locations as part of a separate NEPA process and document. In addition, the USDA Forest Service will
evaluate and analyze the designs and plans for reconstruction of other ramps, picnic sites, and campsites affected during high releases along the Green River. Such facilities will also be relocated pending funding. The USDA Forest Service environmental document will tier to the DEIS for the operation of the Flaming Gorge Dam, as appropriate, relating to environmental, social, and economic resources and issues.

The USDA Forest Service, Reclamation, and other concerned Federal and State agencies will cooperate during the preparation of the referenced environmental document for the relocation of the trail and related facilities to ensure that issues are addressed for the operation of the dam, riverflows, user safety, and protection of natural and physical resources. Reclamation will support the USDA Forest Service in obtaining funding through the USDA Forest Service budgeting process that will be needed to complete the USDA Forest Service environmental document and the relocation of the trail and related facilities.

S.10.2.4 Browns Park Highway Environmental Impact Statement

An EIS is currently being prepared for a Daggett County, Utah, proposal to realign and pave Browns Park Road from its junction with U.S. 191 in Utah to Colorado Route 318. The existing, unpaved 16.8-mile long segment of road crosses BLM, State, and private lands. Scoping meetings were held by the Federal Highway Administration, Utah Department of Transportation, and BLM in December 1999.

S.10.2.5 Resource Management Plans

The BLM Vernal Field Office is preparing to scope the draft resource management plan (RMP)/EIS for approximately 1.8 million acres in northeastern Utah. This plan, known as the Vernal Resource Management Plan, will combine the existing Diamond Mountain and Book Cliffs RMPs into a single plan. The final EIS is scheduled to be completed in March 2005.

The Ashley National Forest began revisions in March 2004 of its Land and Resource Management Plan, commonly referred to as Forest Plan. The process for revision of this plan, including NEPA compliance, is expected to take 4 to 5 years.

S.10.2.6 Federal Reserve Water Rights

Canyonlands National Park and Dinosaur National Monument have inchoate (pending use) Federal water rights to the Green River. However, the National Park Service is not actively working with the State of Utah to quantify those rights. Future plans for quantification are uncertain.
S.11 DESCRIPTION OF ALTERNATIVES

Under the No Action Alternative, Flaming Gorge Dam would be operated to achieve the flow and temperature regimes recommended by the 1992 Biological Opinion on the Operation of Flaming Gorge Dam. Depending upon the hydrologic conditions of the upper Green River Basin, forecasted flows on the Yampa River would be supplemented by releases from Flaming Gorge Dam designed to achieve the peak flow, duration, and base flow (riverflows not associated with snowmelt runoff) recommendations described in the 1992 Biological Opinion.

Under the Action Alternative, Flaming Gorge Dam would be operated to achieve the flow and temperature regimes recommended in the 2000 Flow and Temperature Recommendations.

S.11.1 Development of Alternatives

S.11.1.1 Criteria Used to Select Alternatives

Potential alternatives analyzed in the DEIS were studied to determine whether they could meet the purpose of and need for the Proposed Action. A number of scenarios for dam operation, originally thought to be viable alternatives, were determined to be more accurately described as possible subsets of the Action Alternative. Because of the inherent need for operational flexibility in dam operations, as acknowledged by and incorporated into the 2000 Flow and Temperature Recommendations, and because any potential impacts from discreet operational scenarios are already captured by analysis of the Action and No Action Alternatives, it was determined that analyzing subtle differences in dam operations as separate alternatives would not yield meaningful information for the public or the decisionmaker.

Alternatives that are included in this analysis are those which both:

- Meet flow and temperature recommendations as described in the 2000 Flow and Temperature Recommendations.
- Maintain all authorized purposes of the Flaming Gorge Unit of CRSP.

S.11.1.2 Alternatives Considered but Eliminated From Detailed Study

S.11.1.2.1 Modified Run of the River Alternative – During the scoping process, the National Park Service and others requested consideration of a Run of the River Alternative. Under such an alternative, dam releases would match the reservoir inflow (unregulated) to provide a more natural flow regime including more natural variations in the daily flows of the Green River below Flaming Gorge Dam. Further analysis of this alternative led to the establishment of a Modified Run of River Alternative, where dam releases equaled 87 percent (%) of the unregulated inflow to the reservoir. This provided reservoir operators the ability to store 13% of the spring inflow volume for release to meet project purposes and flow recommendations at other times of the year. The 87% level was chosen because it was the highest percentage that provided enough water
storage to achieve the base flow ranges recommended in the 2000 Flow and Temperature Recommendations. Percentages higher than 87% could not achieve the recommended base flows of the 2000 Flow and Temperature Recommendations.

Preliminary analysis of the historic inflows into Flaming Gorge did show that it might be possible to operate Flaming Gorge using a “Modified Run of River” approach to achieve the 2000 Flow Recommendations during the spring. However, it was learned through this study that the effect of water consumption above Flaming Gorge played a much more significant role than was originally thought. The Flaming Gorge model did account for the inevitability that water consumption will increase in the future. The Consumptive Uses and Losses Report, published by Reclamation, estimates that current water consumption above Flaming Gorge Reservoir is about 450,000 acre-feet per year. This is about 25% of the mean annual unregulated inflow into Flaming Gorge Reservoir. In addition to the level of water consumed, irrigation diversions, which are not entirely consumed, occur most often during the months of May through August. Such diversions are not usually completely consumed, there is a lag period before the water returns to the river. Sometimes this lag period can be as long as several months. Water consumption and diversions can significantly decrease the unregulated inflow peaks that occur during the spring. As a result, the “Modified Run of River” approach released less water than would have been released under natural conditions. For this reason, the “Modified Run of the River” could not achieve the spring flow objectives of the 2000 Flow and Temperature Recommendations.

Water consumption on the Green River has an ever increasing effect on the inflows (and unregulated inflows) to Flaming Gorge Reservoir. Consequently, water consumption will further complicate Reclamation’s ability to achieve the 2000 Flow and Temperature Recommendations in the future. This modeling study indicated that, in the case of a “Modified Run of River” approach for operating Flaming Gorge Dam, the current level of water consumption in the Green River Basin already makes it too difficult to achieve the 2000 Flow and Temperature Recommendations without having significant negative impacts on the other resources associated with Flaming Gorge Reservoir. Based on these findings, the “Modified Run of River” approach was not considered a viable alternative that could be included for analysis in the Flaming Gorge Environmental Impact Statement.

S.11.1.2.2 Decommissioning and Removing Flaming Gorge Dam – During the scoping process, a request was made to consider decommissioning the dam as an alternative to allow endangered fish to recover. This alternative was not selected for detailed study in the DEIS because it does not meet the purpose of and need for the Proposed Action. Specifically, decommissioning the dam would prevent continuing the authorized purposes of the dam under the Colorado River Storage Project and the Flaming Gorge National Recreation Area authorizing legislation, among others.

S.11.1.3 Summary of Alternatives Analyzed in the Flaming Gorge Environmental Impact Statement

S.11.1.3.1 No Action Alternative – Under the No Action Alternative, Flaming Gorge Dam would be operated to achieve the flow and temperature regimes recommended in the 1992 Biological Opinion. These flows were intended to mimic a more natural hydrograph than occurred under previous dam operations and to protect nursery habitats of endangered fishes downstream from the Yampa River confluence.
Under normal operations, reservoir releases through Flaming Gorge Powerplant range from 800 to 4,600 cfs. These flows adhere to the interim operating criteria for Flaming Gorge Dam established by Reclamation in September 1974. Under these criteria, Reclamation agreed to provide (1) a minimum flow of 400 cfs at all times, (2) flows of 800 cfs under normal conditions and for the foreseeable future, and (3) flows exceeding 800 cfs when compatible with other CRSP reservoir operations.

Temperature requirements under the No Action Alternative, specified in the Reasonable and Prudent Alternative of the 1992 Biological Opinion (p. 30), include the following:

Releases from Flaming Gorge beginning July 1 and continuing until November 1 should be of the warmest water available, approaching 59 degrees F (15 degrees C) (highest lake levels). By releasing the warmest water available during this period, water temperatures in the upper Green River should not differ more than 9 degrees F (5 degrees C) in the Yampa River at Echo Park and should average near 72-77 degrees F (22-25 degrees C) in Gray Canyon from July 1 to August 15.

S.11.1.3.2 Action Alternative – Under the Action Alternative, releases from Flaming Gorge Dam would be patterned so that the peak flows, durations, and base flows and temperatures, described in the 2000 Flow and Temperature Recommendations for Reaches 1, 2, and 3 of the Green River, would be achieved.

- Reach 1 begins at Flaming Gorge Dam and extends 65 river miles to the confluence of the Green and Yampa Rivers. In this reach, the Green River meanders about 10 river miles into northwestern Colorado and then flows southward for about 30 river miles. This reach is almost entirely regulated by releases from Flaming Gorge Dam.

- Reach 2 begins at the confluence of the Green and Yampa Rivers in Colorado and extends 99 river miles southwest to the White River confluence near Ouray, Uintah County, Utah. In this reach, tributary flows from the Yampa River combine with releases from Flaming Gorge Dam to provide a less regulated flow regime than in Reach 1.

- Reach 3 begins at the confluence of the Green and White Rivers and extends 246 river miles south to the confluence of the Green and Colorado Rivers in Canyonlands National Park at the boundary of Wayne and San Juan Counties in southeastern Utah. In this reach, the Green River is further influenced by tributary flows from the White, Duchesne, Price, and San Rafael Rivers.

Table S-1 shows a summary of the recommended spring peak and summer-to-winter base flows from the 2000 Flow and Temperature Recommendations report for all three reaches of the Green River. Under the Action Alternative, Flaming Gorge Dam would be operated with the goal of achieving the 2000 Flow and Temperature Recommendations while maintaining and continuing all authorized purposes of Flaming Gorge Dam and Reservoir.

The 2000 Flow and Temperature Recommendations for each reach are not integrated in such a way that a particular release from Flaming Gorge Dam could equally achieve the recommendations for all reaches simultaneously. The intent of the Action Alternative is first to meet the 2000 Flow and Temperature Recommendations for Reach 2 and then, if

1 Recommended flows as measured at the United States Geological Survey gauge located near Greendale, Utah, for Reach 1; Jensen, Utah, for Reach 2; and Green River, Utah, for Reach 3.
2 Wet (0% exceedance): A year in which the forecasted runoff volume is larger than almost all of the historic runoff volumes. This hydrologic condition has a 10% probability of occurrence.
3 Moderately Wet (10–30% exceedance): A year in which the forecasted runoff volume is larger than most of the historic runoff volumes. This hydrologic condition has a 20% probability of occurrence.
4 Average (30–70% exceedance): A year in which the forecasted runoff volume is comparable to the long-term historical average runoff volumes. This hydrologic condition has a 20% probability of occurrence.
5 Moderately Dry (70–90% exceedance): A year in which the forecasted runoff volume is less than almost all of the historic runoff volumes. This hydrologic condition has a 20% probability of occurrence.
6 Dry (90–100% exceedance): A year in which the forecasted runoff volume is less than almost all of the historic runoff volumes. This hydrologic condition has a 10% probability of occurrence.
7 Recommended flows > 18,600 cfs (527 m^3/s) in 1 of 2 average years.
8 Recommended flows > 8,300 cfs (235 m^3/s) in other average years.
9 Recommended flows > 22,000 cfs (623 m^3/s) in 1 of 2 average years.
necessary, make adjustments to releases so that the 2000 Flow and Temperature Recommendations for Reach 1 could also be met. The Flaming Gorge Model assumes that the 2000 Flow and Temperature objectives in Reach 3 are met whenever the flow objectives are met in Reach 2.

The 2000 Flow and Temperature Recommendations focus primarily on the flow regimes in Reaches 2 and 3, which include flows from the Yampa River. However, since these river flow criteria are based solely on upper Green River hydrology, the 2000 Flow and Temperature Recommendations in Reaches 1 and 2 would most likely be achieved to varying degrees. For example, in years when the upper Green River Basin is wetter than the Yampa River Basin, meeting the 2000 Flow and Temperature Recommendations in Reaches 1 and 2 would most likely exceed the minimum target for the peak flow recommendations for Reach 1.

Conversely, if the Yampa River Basin is wetter than the upper Green River Basin, meeting the 2000 Flow and Temperature Recommendations for Reaches 2 and 3 could result in falling short of the peak flow target for Reach 1. Under this scenario, the Action Alternative might require Flaming Gorge Dam releases to be increased so that the 2000 Flow and Temperature Recommendations in Reach 1 could also be met. Flows in Reaches 2 and 3 would then exceed their respective minimum 2000 Flow and Temperature Recommendations. Since only one release pattern can be selected each year, depending upon how water is distributed between the upper Green River and Yampa River Basins, each reach would achieve or exceed its respective minimum 2000 Flow and Temperature Recommendations to varying degrees.

Each year, Reclamation would work closely with the U.S. Fish and Wildlife Service and Western in developing a flow regime consistent with the 2000 Flow and Temperature Recommendations and CRSP purposes and would also consider input from the Flaming Gorge Working Group meetings. The overall effectiveness of implementing the Action Alternative would be measured by the long-term frequency of achieving flow thresholds described in the 2000 Flow and Temperature Recommendations. Consideration would be given to hydrologic conditions, operational limitations, and past operational conditions. An administrative record of the operational decisionmaking would be maintained and available to the public. This record would include analysis of previous operations and the effectiveness of achieving desired targets on a year-by-year basis.

Water release temperatures at the dam would be regulated with the objective of achieving target temperatures for upper Lodore Canyon and the confluence of the Yampa and Green Rivers during the first 2 to 5 weeks of the base flow period and/or when Colorado pikeminnow larvae are present at this confluence.

---

**S.12 REVIEW OF FLAMING GORGE MODEL DEVELOPED FOR THE FLAMING GORGE DAM DEIS**

As detailed in the DEIS, a river simulation model (Flaming Gorge Model) was developed for the Green River system to assess impacts of Flaming Gorge Dam operations. For
both of the alternatives analyzed in the DEIS, the model predicts the water surface elevation of Flaming Gorge Reservoir as well as the flows in the Green River at various points downstream from the dam.

Under the No Action Alternative, the bypass tubes would be used in 23% of all years, and the spillway would be used in 5% all of years. In comparison, for the Action Alternative, the Flaming Gorge Model predicts more frequent use of the bypass tubes and spillway at Flaming Gorge Dam. Under the Action Alternative, the Flaming Gorge Model predicts that the bypass tubes would be used in 50% of all years, and the spillway would be used in 29% of all years.

A review of the Flaming Gorge Model was performed by three authors of the 2000 Flow and Temperature Recommendations to evaluate whether the degree of bypass and spill predicted by the Flaming Gorge Model would be necessary. The main focus of the model review was the frequency of bypass and spillway use. The reviewers also examined the model's behavior and evaluated how the model simulated the year-round operation of Flaming Gorge Dam.

In most situations, the reviewers found that the Flaming Gorge Model properly simulates the operation of Flaming Gorge Dam. The reviewers found that the Flaming Gorge Model performs well in dry, moderately dry, and average years; however, the review showed that the model appeared to bypass or spill more water than may be necessary in some moderately wet and wet years.

The lack of flexibility within the operational rules of the model was the main reason bypasses and spills were higher than necessary in the Flaming Gorge model. While many model rules allow for decision trees, a model such as the Flaming Gorge Model cannot adjust to all situations or consider the balance of all available operating options.

Reclamation acknowledges that the Flaming Gorge Model may overstate bypasses and therefore may overstate potential effects that result from the bypassing of water. Reclamation also notes that while the Flaming Gorge Model provides good information to assess potential effects, details and flexibility that cannot be captured by modeling will be factored into operational decisionmaking each year.

S.13 OPERATIONAL DESCRIPTION

The following discussion provides further clarification on operations under the No Action Alternative and the Action Alternative, while maintaining the authorized purposes and ensuring safe operations of Flaming Gorge Dam under normal operational conditions. As noted in section S.6, operational plans could change due to malfunction of the dam and powerplant equipment and during public emergencies.

S.13.1 Safe Operation of Flaming Gorge Dam

Safe operation of Flaming Gorge Dam is of paramount importance and applies to both the No Action Alternative and Action Alternatives. To safely and efficiently operate
Flaming Gorge Dam, forecasted inflows must be incorporated into the decisionmaking process. A description of this process is provided in section 1.5 of the DEIS.

Inflow forecasts generated by the National Weather Service each month are used by Reclamation to plan future reservoir operations. These forecasts have some degree of error associated with them which can impact the safe operation of a reservoir. Forecast errors are attributable mostly to hydrologic variability and, to a much lesser degree, the forecasting procedure. For this reason, forecast errors will always be a factor associated with the operation of Flaming Gorge Reservoir.

Analysis of the historic forecast errors at Flaming Gorge provide the basis for estimating safe upper limit operating reservoir levels at various times of the year under varying hydrologic conditions. From this analysis, 1% exceedance forecast errors were generated and used in routing studies designed to establish safe upper limit reservoir levels. A 1% exceedance error can be expected to occur about 1% of the time or about 1 year out of every 100 years.

Safe operation of Flaming Gorge provides enough storage space in the reservoir at all times throughout the year, such that the volume of a 1% exceedance forecast error can be absorbed by the reservoir. In other words, the safe operation of Flaming Gorge Reservoir must assure that 99% of the foreseeable forecast errors can be successfully routed through the reservoir without uncontrolled spills occurring. For this reason, the reservoir elevation is intentionally drawn down during the fall and winter months.

The upper limit drawdown levels established as safe operating parameters for Flaming Gorge Reservoir under various hydrologic conditions were determined through the routing studies, and are shown in table S-2. These upper limit drawdown levels apply to both the No Action and Action Alternatives.

S.13.2 Reservoir Operations Process Under the No Action Alternative

S.13.2.1 Operations in May Through July (Spring Period)

Under the No Action Alternative, the April through July unregulated inflow forecast and the condition of the reservoir, would be used to establish the magnitude and duration of a spring peak release for the current year. The magnitude of the spring release would normally be from 4,000 cfs to powerplant capacity (about 4,600 cfs), unless hydrologic
conditions indicated that bypasses or spills would be necessary for safe operations of the dam. Bypasses or spills would be timed to occur when the Yampa River peak flows and immediate post peak flows occur.

Reclamation would establish a range of spring operational scenarios, through consultation with the U.S. Fish and Wildlife Service and Western. These scenarios would achieve the objectives of the Reasonable and Prudent Alternative of the 1992 Biological Opinion on the Operation of Flaming Gorge Dam under one of three hydrologic conditions (dry, average, or wet). The range of scenarios would provide flexibility in operations to adjust to changing hydrologic conditions and would be based on the probable minimum and probable maximum inflow forecasts issued in April by the River Forecast Center. Timing of the spring peak release under the range of possible operational scenarios would occur with the peak flows and immediate post peak flows on the Yampa River.

When the hydrologic condition is determined to be dry, the spring peak duration would be 1 to 2 weeks. Most likely, the magnitude of the release during the spring peak in dry years would be limited to powerplant capacity and could be limited to 4,000 cfs to conserve reservoir storage. In dry years, the spring peak release would be completed no later than June 20.

When the hydrologic condition is determined to be average, the spring peak duration would be 2 to 5 weeks. The magnitude of the release during the spring peak most likely would be limited to powerplant capacity (about 4,600 cfs). The spring peak release in average years would be completed by July 10.

Wet hydrologic conditions would establish a spring peak duration of 5 weeks or greater. Peak releases in wet years could include bypass releases and possibly spillway releases, depending on conditions at Flaming Gorge Reservoir. The use of bypass tubes or the spillway would be based on the safe operating criteria for the dam. The magnitude of peak releases in wet years would be at least powerplant capacity (about 4,600 cfs) and the spring peak release in wet years would be completed by July 20.

S.13.2.2 Use of Bypass Tubes and Spillway at Flaming Gorge Dam

Under the No Action Alternative, the use of the bypass tubes or the spillway would occur only when hydrologically necessary to maintain safe operations of Flaming Gorge Dam, during emergency operations, or when the full release capacity of the powerplant is unavailable. For the No Action Alternative, under normal operations, the magnitude of peak releases for endangered fish would be limited to powerplant capacity (about 4,600 cfs). However, if Reclamation determines that bypass releases would be likely for hydrologic reasons, Reclamation would attempt to schedule these bypass releases to occur with the peak flows and immediate post peak flows of the Yampa River.

S.13.2.3 Summer and Fall Operations (Early Base Flow Period)

Under the No Action Alternative, after the spring peak release is completed, releases from Flaming Gorge Dam would be reduced so that flows of the Green River, measured at Jensen, Utah, would achieve a target flow ranging from 1,100 to 1,800 cfs. Daily average flows would be maintained as close to this target as possible until September 15.
After September 15, releases from Flaming Gorge Dam could be increased so that the daily average flow measured at Jensen, Utah, would achieve a target ranging from 1,100 to 2,400 cfs while controlling the reservoir elevation within safe operating levels.

During the early base flow period (through the month of October), fluctuating releases for power production likely would occur. These fluctuating releases would be limited so that the hourly flow of the Green River, measured at Jensen, Utah, would be maintained at ±12.5% of the daily average flow of the Green River (measured at Jensen, Utah).

\[ \text{S.13.2.4 Winter Operations (Late Base Flow Period)} \]

There are no specific flow recommendations provided by the 1992 Biological Opinion for the period from November to May. Beginning November 1, the 1992 Biological Opinion calls for releases to be low and stable near historic levels. Under the No Action Alternative, Flaming Gorge daily average releases from November through May potentially could range from 800 cfs to powerplant capacity (about 4,600 cfs). However, it is anticipated that in most years, releases during this period would range from 800 cfs to about 3,000 cfs. Releases from Flaming Gorge Dam during the late base flow period would be designed to reduce the reservoir elevation to maintain safe reservoir operations.

Under the No Action Alternative, releases would achieve an upper limit drawdown elevation on March 1 of 6027 feet above sea level. The upper limit drawdown elevations for May 1 under the No Action Alternative are the same as those under the Action Alternative.

During the late base flow period, fluctuating releases for power production could likely occur. The Reasonable and Prudent Alternative of the 1992 Biological Opinion does not specifically limit fluctuating releases during the late base flow period. Under the No Action Alternative, however, fluctuating releases would be limited, similar to the early base flow period, as they have been historically. The hourly flow of the Green River measured at Jensen, Utah, would be maintained from ±12.5% of the daily average flow measured at Jensen, Utah.

\[ \text{S.13.3 Reservoir Operations Process Under the Action Alternative} \]

In general, implementation of the 2000 Flow and Temperature Recommendations into the operational plans for Flaming Gorge Dam would occur through coordination as described on pages 5-8 of the 2000 Flow and Temperature Recommendations. A Technical Working Group consisting of biologists and hydrologists involved with endangered fish recovery issues would be convened by Reclamation at various times throughout the year. Staff from Reclamation, Fish and Wildlife, and Western would be members of this group as well as other qualified individuals who choose to participate on a voluntary basis. Reclamation would present an initial operational plan with balanced consideration of all resources associated with Flaming Gorge Reservoir and the Green River for comment from the Technical Working Group. Reclamation would take into consideration the information described in table S-4 and any new information that may be available to

---

\[ ^{1} \text{The daily average flow measured at Jensen, Utah, would be determined from the average of the instantaneous flow readings during a 24-hour period from midnight to midnight each day.} \]
refine the plan to best meet the needs of the endangered fish. Reclamation would comply with ESA Section 7 consultation requirements and may make refinements to the plan based on the comments from the Technical Working Group. Reclamation could then present the new plan to the Flaming Gorge Working Group for additional comments. Reclamation could further refine the plan based on information gathered at the Flaming Gorge Working Group Meeting. This process would ensure that the 2000 Flow and Temperature Recommendations and the authorized purposes of Flaming Gorge Dam are considered in a balanced and fair manner as the operational plan is developed.

Reclamation's meetings with the Technical Work Group would also provide an opportunity to discuss historic operations in terms of the accomplishments and shortcomings of meeting the 2000 Flow and Temperature Recommendations. Reclamation would maintain an administrative record of these meetings to document the planning process.

S.13.3.1 Operations in May Through July (Spring Period)

Under the Action Alternative, Reclamation would establish a hydrologic classification for the spring period (May through July) based on the April through July forecasted unregulated inflow volume. This forecast is issued by the River Forecast Center beginning in early January and is updated twice per month until the end of July. During the spring period, Reclamation would classify the current hydrology of the Green River system into one of the five hydrologic classifications described in the 2000 Flow and Temperature Recommendations (wet, moderately wet, average, moderately dry, and dry). Table S-3 describes the percent exceedance ranges that would be used for each classification under the Action Alternative.

<table>
<thead>
<tr>
<th>Hydrologic Classification</th>
<th>Percentage Exceedance Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wet</td>
<td>&lt;10</td>
</tr>
<tr>
<td>Moderately Wet</td>
<td>30 to 10.1</td>
</tr>
<tr>

<td>70 to 30.1</td>
</tr>
<tr>
<td>Moderately Dry</td>
<td>90 to 70.1</td>
</tr>
<tr>
<td>Dry</td>
<td>&gt;90</td>
</tr>
</tbody>
</table>

The hydrologic classification would be used to establish the range of flow magnitudes and durations that could potentially be targeted for the approaching spring release period. These targets would be incorporated into a spring operations plan. This plan would be prepared each year by Reclamation under consultation with the U.S. Fish and Wildlife Service and Western and in coordination with the Technical Working Group before the spring Flaming Gorge Working Group meeting. The factors listed in table 5.3 of the 2000 Flow and Temperature Recommendations (shown as table S-4), along with the established hydrologic classification, would be considered in the development of the operations plan.

Source: 2000 Flow and Temperature Recommendations, table 5.3.

In most years, it is expected that the flow magnitudes and durations achieved in Reach 2 each spring would be consistent with the flow magnitudes and durations described in the 2000 Flow and Temperature Recommendations for the hydrologic classification established in May of each year. However, because the factors listed in table S-4 are also considered, particularly runoff conditions in the Yampa River, there would be some years where the peak flows that occur in Reach 2 achieve the targets for either one or two classifications higher (wetter) or one classification lower (drier) than the actual classification established for the Green River.

It is anticipated that in some years, when the hydrologic classification for the Green River is average, factors listed in table S-4 could occur such that it would be possible to achieve the targets established for either the moderately wet or wet classifications. Conversely,
there would be some years classified as moderately wet when the conditions of these factors in table S-4 would be such that targets established for the wet or average classification would be met. There could also be years classified as wet where moderately wet targets would be achieved because of the conditions of these factors. It would be the responsibility of Reclamation to ensure that, over the long term, Flaming Gorge Dam and Powerplant are operated consistent with the 2000 Flow and Temperature Recommendations.

The operations plan would describe the current hydrologic classification of the Green River Basin and the hydrologic conditions in the Yampa River Basin, including the most probable runoff patterns for the two basins. The operations plan would also identify the likely Reach 2 flow magnitudes and durations that would be targeted for the upcoming spring release. Because hydrologic conditions often change during the April through July runoff period, the operations plan would contain a range of operating strategies that could be implemented. Flow and duration targets for these alternate operating strategies would be limited to those described for one classification lower or two classifications higher than the classification for the current year.

The spring operations plan would be presented to the Flaming Gorge Working Group each spring for discussion. Reclamation could modify the plan based on information gathered at the Flaming Gorge Working Group meeting.

In years classified as wet, bypass releases would usually be required both to operate the dam safely and to meet the 2000 Flow and Temperature Recommendations. Releases above powerplant capacity would be expected to be made for a period of about 4 to 9 weeks. The exact magnitude of the release and duration of the release would depend upon factors identified in table S-4. Wet years, high releases would be expected to occur from mid-May to early July (and, in very wet years, through July). The bypass and spillway releases, required in wet years, would be timed with the objective of meeting Reach 2 wet or moderately wet year targets, depending upon the hydrologic conditions in the Yampa River. The initiation of bypass and spillway releases would take place in mid- to late May coincident with the Yampa River peak. In extremely wet years, releases above powerplant capacity could be initiated in April or early May before the Yampa River peak.

In years classified as moderately wet, bypass releases usually (but not always) would be required for safe operation of the dam and to meet the 2000 Flow and Temperature Recommendations. Occasionally, some use of the spillway also might be required in moderately wet years for safe operation of the dam. The volume of the powerplant bypass in moderately wet years would be less than in wet years and would generally occur for a period of about 1 to 7 weeks. The timing of these releases would be from mid- to late May into June and sometimes extend into July. Releases from Flaming Gorge Reservoir in moderately wet years would be timed with the objective of meeting Reach 2 wet, moderately wet, or average year targets, depending upon the hydrologic conditions in the Yampa River basin and the information contained in table S-4.

In years classified as average, bypass releases likely would not be required for safe operation of the dam but periodically would be required to meet the objectives of the 2000 Flow and Temperature Recommendations. In most average years, spring peak releases would be limited to powerplant capacity (about 4,600 cfs) with peak releases taking place for about 1 to 8 weeks, usually in the mid-May to late June (but occasionally extending into July) time period. In about 1 out of every 3 average years, bypass releases
from Flaming Gorge would be required to achieve the Reach 2 flow recommendation peak and duration targets. In these years, the objective would be to achieve targeted flows in Reach 2 of 18,600 cfs for 2 weeks. To conserve water, bypass releases in these average years would be made only to the extent necessary to achieve this target. It can be expected that bypass releases, when required to meet the 2000 Flow and Temperature Recommendations in average years, would be implemented for a period of less than 2 weeks. In some years classified as average, the targets achieved during the spring would be moderately wet or wet as a result of flows on the Yampa River that exceeded forecasted levels.

The objective in dry and moderately dry years would be to conserve reservoir storage while meeting the desired peak flow targets in Reach 2 as specified in the 2000 Flow and Temperature Recommendations. The bypass tubes and the spillway would not be used to meet flow targets in moderately dry and dry years but, on rare occasion, might be needed to supplement flows that cannot be released through the powerplant because of maintenance requirements. In dry years, a powerplant capacity release of 1 day to 1 week would occur during the spring, and this release would be timed with the peak of the Yampa River. In moderately dry years, a 1- to 2-week powerplant capacity release would occur during the spring and would be timed with the peak and post peak of the Yampa River.

S.13.3.2 Use of Bypass Tubes and Spillway at Flaming Gorge Dam

The bypass tubes and the spillway at Flaming Gorge Dam have been utilized historically, as needed, for safe operation of the dam. In years with high inflow, bypass releases, and sometimes spillway releases, may be required under the Action Alternative to meet the 2000 Flow and Temperature Recommendations. Bypass and spillway releases, required for safe operation of the dam and to meet the 2000 Flow and Temperature Recommendations, would be scheduled coincident with Yampa River peak and post peak flow (the mid-May to mid-June time period) with the objective of meeting flow recommendation targets in Reach 2.

There would be some years (moderately wet years and average years) when use of the bypass would not be required for safe operation but would be needed to meet the 2000 Flow and Temperature Recommendations. As part of the annual planning process discussed above, Reclamation would consult with the U.S. Fish and Wildlife Service and Western and coordinate with the Technical Working Group to make a determination whether bypasses should be attempted to achieve the targeted Reach 2 magnitudes and durations.

S.13.3.3 Operations in August Through February (Base Flow Period)

Under the Action Alternative, during the base flow period, Reclamation would classify the current hydrology of the Green River system into one of the five hydrologic classifications described in the 2000 Flow and Temperature Recommendations (wet, moderately wet, average, moderately dry, and dry). For the month of August, the hydrologic classification would be based on the volume of unregulated inflow during the spring period. For the months of September through February, the percentage exceedance would be based on the previous month's volume of unregulated inflow. If the unregulated inflow during the previous month falls into a different hydrology
classification than the assigned hydrology classification for the previous month, then the classification could be shifted by one classification (up or down) to reflect the change in hydrology. A shift would only be made when the reservoir condition indicated that the shift would be necessary to achieve the March 1 drawdown level of 6027 feet above sea level. Otherwise, the hydrologic classification for the current month would remain the same as for the previous month.

The range of acceptable base flows for Reach 2 would be selected from the 2000 Flow and Temperature Recommendations for the hydrologic classification set for the current month. Reclamation would make releases to achieve flows in Reach 2 within the acceptable range and also ensure that the reservoir elevation on March 1 would be no higher than 6027 feet above sea level.

The 2000 Flow and Temperature Recommendations during the base flow period do allow for some flexibility, and the Action Alternative accommodates this flexibility. Under the Action Alternative, the flows occurring in Reach 2 during the base flow period would be allowed to vary from the targeted flow by ±40% during the summer to fall period (August through November) and by ±25% during the winter (December through February), as long as the day-to-day change is limited to 3% of the average daily flow and the variation is consistent with all other applicable 2000 Flow and Temperature Recommendations. Reclamation would utilize the allowed flexibility to the extent possible, to efficiently manage the authorized resources of Flaming Gorge Dam. Flaming Gorge Reservoir would be operated through the base flow period so that the water surface elevation would not be greater than 6027 feet above sea level on March 1.

During the base flow period, hourly release patterns from Flaming Gorge Dam would be patterned so that they produce no more than a 0.1-meter stage change each day at the Jensen gauge, except during emergency operations.

S.13.3.4 Operations in March and April (Transition Period)

From March 1 through the initiation of the spring peak release (typically, this occurs in mid- to late May), there are no specific flow requirements specified in the 2000 Flow and Temperature Recommendations. For the Action Alternative, releases during this transition period would be made to manage the reservoir elevation to an appropriate drawdown level based on the forecasted unregulated inflow. Appropriate drawdown levels under normal operations during the transition period are those that would allow for safe operation of the dam through the spring. The upper limit drawdown levels for varying percentage exceedances are described in table S-5. These drawdown levels apply for both the Action and the No Action Alternatives.

Table S-5 implies that upstream regulation above Flaming Gorge Reservoir remains relatively consistent with historic regulation. In the event that less storage space would be available above Flaming Gorge Reservoir during the spring, these drawdown levels may have to be lower than those specified in table S-5 for safe operation of Flaming Gorge Dam. In extreme wet years, the drawdown level for May 1 could potentially be lower than what is specified to maintain safe operation of the dam.

---

2 Historically (1988-2003), there generally has been about 200,000 acre-feet of available space at Fontenelle Reservoir (above Flaming Gorge) on May 1.
Table S-5.—Upper Limit Drawdown Levels

<td>6027</td>
</tr>
</tbody>
</table>

Reclamation would determine the appropriate reservoir drawdown based on the percentage exceedance of the forecasted inflow volume during the spring (April through July). The forecast is issued twice during March and twice during April. Under normal operations during the transition period, releases would be limited to a range from 800 cfs to powerplant capacity (4,600 cfs).

Hourly releases during the transition period would be patterned so that they are consistent with the hourly release patterns established during the preceding base flow period. The 2000 Flow and Temperature Recommendations do not address hourly patterns during the transition period. During the transition period, Reclamation would maintain the same fluctuation constraints as in the preceding base flow period to provide operational consistency as has been done historically.

S.14 ENVIRONMENTAL CONSEQUENCES

This section summarizes the DEIS analyses and comparisons of predicted environmental effects under both the Action and No Action Alternatives.

S.14.1 Hydrology

Tables S-6, S-7, and S-8 present the key flow parameters and ranges described in both the 1992 Biological Opinion (No Action Alternative) and the 2000 Flow and Temperature Recommendations (Action Alternative) under dry, average, and wet hydrological conditions. The 2000 Flow and Temperature Recommendations report also provides recommended flow regimes for moderately wet and moderately dry hydrologic conditions; however, because the 1992 Biological Opinion does not address these conditions, they have been omitted from this comparative analysis.

The 1992 Biological Opinion does not specifically define the differences between wet, average, and dry hydrological conditions but rather, suggests that Reclamation and the U.S. Fish and Wildlife Service consult each year to make this determination. The 2000 Flow and Temperature Recommendations are more specific about how the hydrology of the upper Green River Basin is to be characterized.

</tr>
</tbody>
</table>
The hydrologic conditions of the upper Green River Basin, as described in the 2000 Flow and Temperature Recommendations, are based on the forecasted or actual volume of unregulated inflow (adjusted for storage in upstream reservoirs) into Flaming Gorge Reservoir during the period from April through July. During the spring and early summer, operational decisions would be based on forecasted inflows. After August 1, operational decisions would be based on the measured inflows that occurred during the previous month as well as on the previous April through July period.

For purposes of this analysis, and as defined by the 2000 Flow and Temperature Recommendations, dry conditions in the Upper Green River Basin are identified as unregulated April-July inflow volumes that are exceeded in 9 out of every 10 years (90% exceedance value). The year 1977 was historically dry at which time the unregulated April through July inflow measured only 254,000 acre-feet. In contrast, wet conditions in the upper Green River Basin are identified as unregulated April through July inflow volumes that are exceeded in only 1 out of every 10 years (10% exceedance value). For example, 1986 was a historically wet year at which time the unregulated April through July inflow measured 2,224,000 acre-feet.

S.14.2 Water Quality, Water Temperature, and Sediment Transport

When the operation of Flaming Gorge Dam was changed to meet the requirements of the RPA of the 1992 Biological Opinion, the frequency of summer and fall reservoir drawdowns that produced algal blooms was reduced. This operational change improved the water quality of Flaming Gorge Reservoir. The analysis of the effects of the Action and No Action Alternatives shows that the frequency of reservoir drawdowns likely would not differ from drawdown conditions observed since 1992. Under both alternatives, reservoir drawdowns during drought conditions would cause larger algal blooms. As an example, such a condition occurred in the fall of 2002.

For the Green River below Flaming Gorge Dam, the only water quality issue of concern with respect to the Action Alternative is water temperature. The No Action Alternative would result in future water temperatures based on the recommendations of the 1992 Biological Opinion. Under the Action Alternative, release temperatures and river temperatures in Reach 1 would be somewhat warmer in order to meet the temperature recommendation of 64 degrees Fahrenheit (°F) (18 degrees Celsius [°C]) or greater in upper Lodore Canyon. Reaches 2 and 3, because of their distance from Flaming Gorge Dam, would likely have similar water temperatures under either of the alternatives.

Sediment transport is presented in the Water Quality section of the DEIS because it is an important function in the river system, with the potential to affect both riverine and riparian habitat. Table S-9 illustrates the average annual sediment transport under the No Action and the Action Alternatives as well as the estimated percent of tonnage increase under each of these alternatives for the May, June, July period.

S.14.3 Hydropower

Hydropower analysis focuses on the potential impacts of the alternatives on powerplant operations at Flaming Gorge Dam. This analysis used a computer model developed by Argonne National Laboratory in collaboration with Reclamation. The model uses an estimate of the quantity of energy injected into the power grid along with a forecasted

hourly electricity spot price (market price) to determine the economic value for each alternative. The model determined the revenue generated as a result of operating Flaming Gorge Powerplant to achieve each alternative over the period from 2002 to 2026. The revenues for each alternative were then discounted by 5.5% per year so that they reflected their net present value. The total net present value of the revenue generated under each alternative was then compared to determine the economic impacts to power production under the proposed alternatives. The results are summarized in table S-10 and show that the net present value of economic benefits for the No Action Alternative simulation was $403.1 million while generating about 11,904 gigawatt-hours (GWh) of energy. The Action Alternative showed a net present value of about $423.1 million for the 25-year simulation, an increase of $20.0 million (5.0%) over the estimate for the No Action Alternative.

The Action Alternative would generate about 11,374 GWh of energy, about 4.5% less, compared to the No Action Alternative generation. The Action Alternative generates less energy but is able to generate more of the energy during the seasons when market prices were higher, leading to a slightly greater net present value. The Action Alternative has greater benefits with fewer GWh due to the fluctuations in the market price of energy. The Action Alternative calls for more generation in the summer months when energy sells at higher prices than in the fall when the No Action Alternative generates more power. Given recent volatility in historic prices, there is uncertainty associated with future prices. Because there is less total annual power generation with the Action Alternative, use of an alternative price set that does not assume as large a relative seasonal price difference could result in a negative rather than a positive impact. In any case, the impact is considered to be insignificant when the total value of Flaming Gorge generation is considered.

1 Mills per kilowatthour.

In addition to the economic analysis, a financial analysis was performed as described in the DEIS. While an economic analysis shows the impacts on the national economy as a whole, the financial analysis describes the impacts to the customers who purchase wholesale electricity generated at Flaming Gorge Powerplant. The results of this analysis show that, compared to the No Action Alternative, the Action Alternative would not have a significant impact on the rate CRSP power users pay.

### S.14.4 Agriculture

Under both the No Action and Action Alternatives, about 245 acres of cropland in the historic Green River flood plain could be flooded in nearly half of all years. On average, affected lands would be inundated 2 days longer under the Action Alternative, but since this incremental time would not do further crop damage compared with the No Action Alternative, there are no differences in impacts between the two alternatives.

### S.14.5 Land Use

There are no impacts to land use around the Flaming Gorge Reservoir under either alternative. In Reach 1 of the Green River, in wet years, the Action Alternative would have greater impacts to the use of campgrounds and other recreational facilities that have been built in the historic flood plain than would the No Action Alternative. In average hydrology years, the impacts to such facilities would be about the same under either alternative.

Under the No Action Alternative in Reach 2, the effects of the river on land use that have occurred over the past 10 years would continue. Under the Action Alternative, higher flows of longer duration would be expected to occur in wet years. This would result in inundation levels and durations in the historic flood plain that have not occurred in the recent past and consequently a temporary loss of land use in the flood plain on a more frequent basis. In Reach 3, there would not be a significant land use difference under either alternative.
S.14.6 Ecological Resources

Under the No Action Alternative, present conditions would be expected to continue for all flora and fauna around the Flaming Gorge Reservoir and in the Green River.

Under the Action Alternative, both native and nonnative fish in Reach 1 would likely benefit from the 2000 Flow and Temperature Recommendations. There is the potential for both positive and negative effects to trout in the area immediately below Flaming Gorge Dam, though long-term negative effects are not expected. There is also a potential for negative impacts to trout in the Browns Park area if water temperatures in that area exceed 64 degrees Fahrenheit (°F) (18 [degrees Celsius] °C).

Under the No Action Alternative, there would be continued proliferation of wetland plants and island marshes. Due to infrequent flooding, the flood plain forests of the old high water zone would continue to transition to desert. The old-growth cottonwoods would continue the trend of premature dieoff. There would be limited opportunity for establishment of cottonwoods and box elders. Under the Action Alternative, there may be erosion of wetland and riparian vegetation on islands and bars, followed by increased opportunity for cottonwood establishment. Larger floodflows may improve the health of mature cottonwoods.

Invasive species are present in all reaches and are expected to persist under the No Action Alternative. The Action Alternative could accelerate growth of some invasive species along the river. Tamarisk and giant whitetop are two such species that could increase in rate and acreage of invasion in higher flood plain settings under the Action Alternative.

In the short term, birds and animals along the Green River corridor could be negatively impacted by temporary loss of habitat due to increased flooding, but the potential impacts are not expected to be significant. In the long term, birds and animals are expected to benefit from enhancement of riparian vegetation and habitat.

S.14.6.1 Threatened and Endangered Fish

Under the No Action Alternative, existing conditions for the Colorado pikeminnow, humpback chub, and razorback sucker would be expected to continue. For both the No Action and Action Alternatives, conditions for the bonytail chub are assumed to be the same as for the other three endangered fish species. While these species would be expected to benefit from Recovery Program activities other than implementation of the 2000 Flow and Temperature Recommendations, it is believed that continuation of No Action flow regimes would not provide enough benefit to support their recovery. Under the Action Alternative, river conditions are expected to benefit the endangered fish and their designated critical habitat.

S.14.6.2 Other Threatened and Endangered Species

Under the No Action Alternative, continued decline in acreage and health of native riparian vegetation would have negative effects on the southwestern willow flycatcher. Under the Action Alternative, Ute ladies'-tresses could be lost in Reach 1. Suitable habitat may be lost or otherwise become unsuitable. Additional sites of potentially suitable habitat would likely develop at new locations under the Action Alternative.
Long-term increases in cottonwood and native understory vegetation along the river corridor would benefit bald eagle and southwestern willow flycatcher. Other threatened and endangered species are not expected to be affected by either alternative.

Under the No Action Alternative, continued decline in acreage and health of native riparian vegetation would have negative effects on yellow-billed cuckoo and other State sensitive songbirds. The Action Alternative may reverse degradation of riparian vegetation in Reach 2 and upper Reach 3.

S.14.7 Cultural Resources

Adjacent to the reservoir and along the Green River, there would be no effects from dam operations to cultural resources under either alternative.

S.14.8 Paleontological Resources

Adjacent to the reservoir and along the Green River, there would be no effects from dam operations to paleontological resources under either alternative.

S.14.9 Indian Trust Assets

The No Action Alternative would not affect Indian (American Indian) trust assets. The Action Alternative would not affect agriculture and oil and gas production, or other Indian Trust Assets if advance notice is provided on the timing of spring peak flows. There would be no significant difference between effects on Indian Trust Assets under either the Action or No Action Alternatives.

S.14.10 Safety and Public Health

There is public concern over the creation of mosquito habitat along the Green River due to the flow regimes under both alternatives, which are intended to inundate flood plain depressions for the benefit of endangered fish. Under the No Action Alternative, populations of mosquitoes along the river would not increase. In Reach 1, the Action Alternative could result in an increase in mosquito populations along the river. In Reach 2, the Action Alternative also could result in an increase in mosquitoes, though not as large or as often as in Reach 1. As it has in the past, under either alternative, Reclamation would continue to coordinate peak flow releases with State and county officials to minimize the mosquito problem in the Jensen, Utah, area to the extent possible. Under either alternative, mosquito abatement control by the county would continue. In Reach 3, there would not be a difference in the populations of mosquitoes under either alternative.

Public safety on the Flaming Gorge Reservoir is expected to be unchanged under either alternative. Public safety along the Green River could be affected under the Action Alternative due to the potential for higher flows for longer durations. Existing safety procedures for dam operations would continue to be followed, along with notification to the public of scheduled high flows.
S.14.11 Air Quality

There are no significant effects to air quality under either alternative.

S.14.12 Visual Resources

There are no significant effects on visual resources under either alternative.

S.14.13 Environmental Justice

No adverse effects to minority or low-income populations have been identified under either alternative.

S.14.14 Recreation

On average, total water-based river and reservoir visitation within Flaming Gorge National Recreation Area for the Action Alternative is not expected to measurably change compared to visitation under the No Action Alternative (only +0.3% gain). Gains in economic value are expected to be higher (+9.5%) as a result of water levels moving closer to those under preferred conditions.

Under wet and dry conditions, each of which typically occur only 10% of the time, visitation under the Action Alternative and value on the river is expected to decline compared to that under the No Action Alternative, but the decline is more than offset by gains on the reservoir.

S.14.15 Socioeconomic/Regional Economics

The socioeconomic analysis evaluates the effect of changing expenditures on economic activity in the general vicinity of Flaming Gorge National Recreation Area. The economic impact region is defined by Daggett and Uintah Counties in Utah and Sweetwater County in Wyoming. Given the minor effect on local expenditures from changes in hydropower and agricultural production, the analysis focuses exclusively on recreation expenditures. The combined river and reservoir recreation expenditure impacts of the Action Alternative appear to be positive, but minor, under all hydrologic conditions.

S.15 CUMULATIVE IMPACTS

As defined at 40 Code of Federal Regulations 1508.7, a cumulative impact is an impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, regardless of which agency or person undertakes such actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.
The Flaming Gorge DEIS focuses on whether the Proposed Action, considered together with any known or reasonably foreseeable actions, could cause a cumulative effect for any resource.

Human use of the Green River began to have some impact on the riverine environment early in the 19th century. Later, construction of Flaming Gorge Dam (1958 through 1964) resulted in a profound change to the riverine environment, which contributed to the decline of native fish species in the Green River and native vegetation along the Green River. Also, filling of the reservoir inundated cultural and paleontological resources.

The construction of Flaming Gorge Dam established hydropower generation to serve millions of homes in the West, and to provide water storage capability. The creation of Flaming Gorge Reservoir, the establishment of the Flaming Gorge National Recreational Area, and the establishment of the trout fishery below Flaming Gorge Dam constitute significant benefits to recreation and the regional economy.

The conclusion of the resource analysis in the DEIS is that the Action Alternative when compared to the No Action Alternative would have either a small effect or no effect at all. When added to the cumulative effects for each resource, effects were minor or nonexistent and not enough to change direction of any cumulative effect trends. The Action Alternative would have a positive effect for habitat development overall, which should help the four endangered native fish species and other fish species including trout, especially in combination with other actions initiated by the Recovery Program. Negative cumulative effects could include an increased rate of invasion of tamarisk and Giant White top and possibly the displacement of Ute Ladies'-tresses in reach 1. Cumulative effects to power generation have been negative due to past operational changes, and would continue to be negative on balance.

S.16 Uncertainties

The analyses presented in chapter 4 of the DEIS identify impacts to resources based on the best available data. Uncertainties associated with implementing the Action Alternative are discussed in the DEIS, and summarized here.

The authors of the 2000 Flow and Temperature Recommendations recognized uncertainties in their general approach and in specific recommendations (2000 Flow and Temperature Recommendations). Their recommendations are based on a model which assumes that the ecological integrity of river ecosystems is linked to their dynamic character (Stanford et al., 1996; Poff et al., 1997) and that restoring more natural flow and thermal regimes is a key element to rehabilitating an impaired system. The authors recognized as well that the response of the endangered fishes of the Green River to a more natural flow regime and water temperatures remains largely unmeasured and that factors other than modifications to physical habitat are also impacting these species.

S.16.1 Hydrology

Uncertainties regarding the hydrology of Flaming Gorge Dam necessarily involve assumptions the authors made for the Flaming Gorge Model regarding historical river
flow patterns which in their best judgment most nearly represented real conditions, which therefore cannot be fully addressed because as yet such conditions may not have occurred.

Uncertainties associated with the Flaming Gorge Model include the following:

- Determining which years to attempt to achieve the higher-level springtime flow recommendations in Reach 2 of the Green River. Actual basin indicators such as snow levels, temperature, and climate will henceforth be used in making yearly decisions.
- Obtaining matching flows of the Yampa River to achieve precise target levels to within 300 cfs in Reach 2 of the Green River under normal springtime operations.
- Predicting what resource impacts would occur as a result of future water development in the Green River above and below Flaming Gorge Reservoir.
- Achieving the flow objectives for Reach 2 to provide flows high enough to achieve the flow objectives in Reach 3 of the Green River in the future, given the expected increase in water development affecting its tributaries.
- Accounting for the remote possibility that Flaming Gorge Dam could have a physical restriction that might prevent enough water from being released to achieve the 2000 Flow and Temperature Recommendations objectives.

S.16.2 Operational Limitations for Temperature of Water Released From the Dam

The capability of releasing warmer water through the Flaming Gorge Dam selective withdrawal structure is limited at times, because release water is used to cool turbine bearings. How much additional increase to current capabilities in release temperatures could be realized would have to be determined through testing and adjustment of powerplant instruments at Flaming Gorge Dam. (See note regarding recent reservoir temperature modeling, under last bulleted item in 4.19.4.)

S.16.3 Uncertainties Associated With Increased Spillway Use

Increased spillway use under the Action Alternative would produce a greater likelihood for degradation of concrete in the spillway. Reclamation would inspect the spillway following each period of use and evaluate the need for repairs. If damage to the spillway were to become excessive, repairs would be made and usage could be limited to operations necessary to maintain the required hydrology.

S.16.4 Fish Responses to Flow and Temperature Modifications

Uncertainties regarding nonnative fish responses to Flow and Temperature modifications under implementation of the 2000 Flow and Temperature Recommendations include the following:
Determining how nonnative fish would respond to implementation of proposed changes in Flaming Gorge Dam operations. Releases of warmer water could result in the expansion of cool water nonnative fish populations in Reach 1, an area where their current populations are comparatively low. Such releases could also benefit warm water nonnative species in flood plain habitats resulting from increased overbank flooding. Continued monitoring and nonnative fish controls would be required.

Maintaining the necessary base flows to maximize nursery habitats, since base flows vary from year to year as a function of variation in tributary inputs. Also, the effects of within-day fluctuations on nursery habitat conditions warrant further investigation.

Determining the extent to which an increased frequency of bypassing water could result in entrainment of reservoir nonnative species into the Green River. Monitoring could include evaluating the potential for undesirable reservoir fishes, such as smallmouth bass, becoming established in the tailwater (water below the dam).

Attaining desired temperature thresholds could improve Colorado pikeminnow survivorship. Temperature modeling indicates that, during wet years, the river may not warm enough to provide suitable conditions for year-round Colorado pikeminnow use. If warmer water could be released at the dam during wet years, Colorado pikeminnow survivorship might improve due to higher growth rates and larger sizes of the fish.

S.16.5 Uncertainties Associated With Flood Plain Inundation

Peak flows recommended for Reach 2 were intended to provide inundation of flood plain nursery habitats in wetter years and to promote access to those flood plains by newly hatched razorback sucker larvae drifting from upstream spawning areas. This would ensure that razorback sucker juveniles overwintering in flood plains were allowed an opportunity to return to the main channel in subsequent years. The 2000 Flow and Temperature Recommendations recognized that access to flood plain habitats could be achieved through a combination of increased peak flows, prolonged peak flow duration, lower bank or levee heights, and constructed inlets. The report indicated that substantially more flood plain habitat could be inundated with lower peak flows if levees were removed.

Recent information provided in Valdez and Nelson (2004) indicates the area of depression flood plains that are potentially inundated by 13,000 cfs and 18,600 cfs flows is identical (about 2,200 acre) for the first 52 miles downstream of the only known razorback spawning bar in Reach 2 (figure 4-16). At greater distances, 18,600 cfs flows would inundate an additional 1,186 acre of depression flood plains. On the basis of the Valdez entrainment model, very few larvae are likely to be entrained at these distances from the spawning bar, and survival is likely to be low with sympatric nonnative fish populations in these flood plains.

On the basis of this new information, it may be possible that connection and inundation could potentially be achieved with lower peak releases from Flaming Gorge Dam and still occur in 30% more years than with a peak flow of ≥18,600 cfs.
To resolve uncertainties associated with flow and nonflow actions that may be required for flood plain inundation, Reclamation would coordinate these studies through the Recovery Program. These studies would be conducted using an adaptive management approach as described in Section 4.20.

Resolving these uncertainties along with other uncertainties in flow recommendations is a priority of the Recovery Program. The above studies would be incorporated into the flow evaluation process of the Recovery Program.

S.16.6 Riparian/Vegetation

Uncertainties involving the response of invasive species and certain native plant communities to implementation of the Action Alternative include the following:

- The effects of floodflows on tamarisk establishment on post-dam flood plain surfaces in Lodore Canyon, and on new tamarisk establishment at higher elevations.
- The effects of higher base flows, coupled with several years of drought, on tamarisk establishment along base flow elevations.
- The duration and magnitude of floodflows necessary to stimulate a positive response in mature cottonwoods.
- The response of wetland species to the higher base flows of late summer and lower base flows of winter and early spring.

S.17 ADDRESSING UNCERTAINTIES THROUGH ADAPTIVE MANAGEMENT

Uncertainties associated with operating Flaming Gorge Dam under the Action Alternative, summarized above, would be monitored and addressed through an adaptive management process if the Action Alternative is implemented. Adaptive management consists of an integrated method for addressing uncertainty in natural resource management.

The use of adaptive management does not imply establishment of a separately funded and staffed program to oversee operations at Flaming Gorge Dam. Rather, the adaptive management process would be integrated into the current framework of dam operations, while maintaining the authorized purposes of the dam. It would involve using research and monitoring to test the outcomes of modifying the hydrology and temperature of releases from Flaming Gorge Dam. It is expected that such research and monitoring would be achieved within the framework of the ongoing Recovery Program with regard to native fish and undesirable nonnative fish species and related habitat issues. As a participant in the Recovery Program, Reclamation would be involved in any identification or discussion of the need for new tasks within the Recovery Program to address Flaming Gorge Dam operational considerations or experimental flows. Issues associated with the trout fishery would be monitored by the UDWR as part of their management of that fishery and with ongoing consultation and coordination with...
Reclamation through the Flaming Gorge Working Group and interagency communication. As has occurred in the past, proposed releases for experimental purposes that deviate from the prescribed flows would be disclosed to stakeholders, including the various publics, at Flaming Gorge Working Group meetings, and would be closely coordinated with the U.S. Fish and Wildlife Service and the UDWR.

### S.18 ENVIRONMENTAL COMMITMENTS

This section summarizes Reclamation’s future commitments related to the Action Alternative. Commitments 1 through 4 and 8 would apply under either the Action Alternative or the No Action Alternative.

(1) The Flaming Gorge Working Group, which meets two times per year, would continue to function as a means of providing information to and gathering input from stakeholders and interested parties on dam operations.

(2) The adaptive management process would rely on ongoing or added Recovery Program activities for monitoring and studies to test the outcomes of modifying the flows and release temperatures from Flaming Gorge Dam. It would rely on the Flaming Gorge Working Group meetings for exchange of information with the public.

(3) Reclamation would develop a process for operating the selective withdrawal structure consistent with the objective of improving temperature conditions for the endangered native fish. Such a process would include identification of lines of communication for planning and making changes to selective withdrawal release levels; coordination with other agencies; recognition of equipment limitations that may affect the ability to release warmer water; and the costs and equipment impacts associated with operating at higher temperatures.

(4) Reclamation would continue to annually coordinate the peak flow releases from Flaming Gorge Dam with the appropriate Federal, State, and county officials. This would include continued communication with county officials to assist in their mosquito control activities.

(5) As recommended by the Wyoming State Historic Preservation Office, Reclamation would periodically inspect eligible historic properties around Flaming Gorge Reservoir to determine whether there are any effects from the Action Alternative.

(6) Reclamation would consult with Federal, State, and local officials and the interested public to determine whether additional signage or other means of public notification of higher spring river flows is needed.

(7) Reclamation would develop and implement a monitoring plan for Ute ladies’-tresses populations for determination of possible effects from the Action Alternative. The plan would be developed through coordination with the U.S. Fish and Wildlife Service and the National Park Service. This monitoring plan would include aspects designed to further the understanding of the relationship between Ute ladies’-tresses establishment and tamarisk.
(8) Reclamation would continue to participate in the Recovery Program efforts.

(9) Reclamation would support the Recovery Program, in coordination with the U.S. Fish and Wildlife Service and Western, in developing and conducting Recovery Program studies associated with flood plain inundation.

(10) Reclamation would establish the Technical Working Group consisting of biologists and hydrologists involved with endangered fish recovery issues. The Technical Working Group would meet at various times throughout the year to comment and provide input concerning endangered fish needs to Reclamation’s operational plan.
