Megachile Wootonii, sp. n.

♂.—Length about 13 millim.
Moderately robust, black, with rather thin yellowish pubescence. Head ordinary, facial quadrangle about square, face upper to level of antennae with dense cream-coloured pubescence; vertex with large close punctures and thinly clothed with long yellowish hair, with some shorter black ones intermixed; cheeks broad, very thinly pubescent, lower part with a conspicuous broad transverse band of yellowish-white hair; antennae wholly black, last joint broadened and flattened; mandibles tridentate, more or less elongated, fringed beneath with shining yellow hair beyond the bend; a rounded tubercle at base of mandible beneath, tufted with yellowish hair; mesothorax strongly and closely punctured, with thin erect pubescence, yellowish on anterior half, mostly black on posterior half; scutellum and pleura with longer and denser hair, that on the pleura yellowish white; tegulae black; wings dusky hyaline, broadly darker on apical margin; nervures black, second submarginal cell receiving second recurrent nervure a short distance before its apex; legs black, with yellowish-white hair; four hind femora and tarsi ordinary, the tarsi with fulvous hair on inner side; spurs ferruginous; middle coxae ordinary; anterior coxae with a stout tooth, above which at base is a well-defined patch of shining coppery hair; the tooth itself has a pale stripe on one side; anterior femora pale orange ferruginous, with a black apex and a black stripe on outer side from base to apex; posterior tibiae ferruginous within, black without, broadly pale yellowish at apex, with a broad rounded lamina projecting at right angles; posterior tarsi cream-colour; first joint hollowed, canoe-shaped, a little produced at end, but not as far as tip of second joint, its end rounded; the basal two thirds of its inner edge with a narrow fringe of very short fuscous or black hairs; its outer margin near the base within with some very short black hairs, not forming a distinct patch, and easily overlooked; its hind margin with the usual long fringe of pale hair, of which the inner hairs are strongly tipped with black; remaining joints of anterior tarsi gradually diminishing, formed as in allied species; abdomen rather short, fairly broad, nearly parallel-

sided; with thin erect pubescence, yellowish on the first two
segments and the first half of the third, beyond that black, with
a little yellowish intermixed; no tendency to hair-bands; apical
segment with a very broad and deep semicircular emargination;
subapical central teeth placed in a broad triangle, all
large and long, pointed.

Hob. Ruidoso Creek, New Mexico, 7800 feet, July 6,
asleep on a plant doubtfully referred to *Vicia americana*
(E. O. Wooton, 57). I had taken this for *M. fortis*, but it
is perfectly distinct, and is apparently more allied to *M. mela­
nephae*, Smith. The real *M. fortis* was taken by Prof.
Townsend on the west fork of the Gila River, July 16.

*Megachile perihirta*, sp. n.

♂.—Length about 12 millim.

Moderately robust, black, with rather thin yellowish
pubescence. Head ordinary, facial quadrangle a little longer
than broad, slightly narrowed below; face up to level of
antennae with dense cream-coloured pubescence, but the very
closely punctured clypeus, though somewhat hidden beneath
a long projecting supraelypeal fringe, is itself pubescent only
at the sides; vertex with strong close punctures and erect
yellowish pubescence, not mixed with black; cheeks broad,
thinly pubescent, with two oblique bands of white hair on lower
part; antennae wholly black, last joint somewhat flattened,
but hardly broadened; mandibles not elbowed, lower edge with
a conspicuous yellowish-ferruginous stripe; behind base of
mandibles is a broad projecting lamella, with a narrow line of
minute white pubescence on its anterior face; mesothorax dull,
very closely punctured, with erect pubescence not hiding the
surface, nowhere mixed with black; about equally dense and
of the same yellowish colour on scutellum and pleura; tegulae
piceous, closely punctured; wings dull hyaline, broadly dusky
at apex; nervures black, second submarginal cell long,
receiving second recurrent nervure almost at its apex; legs
black, with pale hair; middle femora incrassate, middle tibiae
arcuate; middle tarsi simple, but first joint very pubescent,
and with a long brush of pale hair behind; spurs whitish;
hind tarsi within with copious orange-fulvous pubescence;
first joint of hind tarsi somewhat broadened; anterior coxae
with a strong spine, at base of which is no bright pubescent
patch; anterior femora orange-fulvous, apical two-thirds
black on outer surface, and on inner surface having a black
stripe; anterior tibiae orange-fulvous becoming ferruginous,
pellucid yellowish white at apex, on outer surface with a
Bees of the Genus Megachile. 127

black patch, on inner edge with a black stripe, apex with a small dentiform projection; anterior tarsi cream-colour, somewhat suffused with pale ferruginous, the last joint pale ferruginous; first joint deeply hollowed, but not very broad, not much produced at end, the margins of the hollow fringed with dark rufous hair, the hind margin with the usual long pale fringe, the inner hairs of which are black at ends; second to fourth joints of anterior tarsi successively smaller, almost bilaterally symmetrical; abdomen with very distinct punctures, broad and short, the lateral margins gently concave, clothed with erect yellowish hair, not concealing the surface, not mixed with black, not at all tending to form bands; apex with a small emargination, on each side of which are two or three irregular teeth; apical ventral segment obtusely angled in the middle, with a small tooth on each side.

Hab. Colorado Springs, Colorado, middle of July (Cll. 3571). At the same locality and time I took a form of *M. fidelis*, Cress., a little different from specimens found in New Mexico.

*Megachile Cusadae*, sp. n

$\xi$—Length about $13\frac{1}{2}$ millim.

Black, with dull white pubescence. Head ordinary, but rather large; eyes sage-green; facial quadrangle nearly square, slightly longer than broad, hardly at all narrowed below; face with white hair, absent about the middle of the shining well-punctured clypeus; vertex shining, with large punctures, thinly pubescent, some black hairs just behind the ocelli; cheeks quite hairy, sloping away behind eyes; antennae black (broken at ends in type specimen); mandibles wholly black, no tooth or tubercle behind their base; mesothorax dullish, strongly and closely punctured, thinly clothed with dull white pubescence, some inconspicuous black hairs on hinder part; scutellum quite shiny; tegulae piceous, with minute punctures; wings dusky hyaline, nervures black, recurrent nervures entering second submarginal cell very near its base and apex; anterior coxae with a rather short spine, having a light yellowish patch at apex; anterior femora orange-rufous above and below, black behind, with long white hair, and having a broad black stripe from base to apex in front; anterior tibiae orange-fulvous beneath and at apex, also the anterior half (longitudinally) within, otherwise black; a small erect spine at apex; anterior tarsi light yellow, the last joint blackish except at base; the joints are not much modified, but the second to fourth are oblique, emarginate at end; the first has a rather shallow groove, and all are black
on the inner hind margin behind the long fringe, which is as in the species with highly modified tarsi, and is wholly white viewed from without, but within the hairs are black for their whole length. The four hindmost legs are black; middle tibia with a rufous spine at apex; middle femora quite stout; spurs pale ferruginous; middle tarsi with a very long fringe of white hair behind; hind tarsi with orange-fulvous hairs on inner side; abdomen fairly broad, parallel-sided, punctured, second and third segments more or less depressed at base; first segment broadly excavated, so that the dorsal (as distinguished from the anterior) surface is very small; pubescence very thin, white; the hind margins of the segments with dense white hair-bands, that on the first thin and weak; apex not at all emarginate, irregularly notched on each side of the middle; the three subapical ventral teeth in the same transverse plane, the middle one long and sharp, the lateral ones short, broad, and blunt.

Hab. Las Cruces, New Mexico. One in the collection of the New Mexico Experiment Station, probably collected by Prof. Townsend. It had been studied by Miss J. E. Casad, who left some descriptive notes.

The following table separates the males of Megachile with peculiar front tarsi which are found in New Mexico, including also the species from Colorado described above. All have spines on the anterior coxae.

Bees of the Genus Megachile.

Pubescence of thorax fulvous .......... fortis, Cress.
7. Anterior legs slender; anterior tarsi with basal joint merely expanded into a flat lamina at the side .................... occidentalis, Fox.
Larger; anterior femora stout, subtriangular in section ................ 8.
8. Anterior femur yellow where it touches tibia; pubescence of face yellowish; a white band of pubescence at scutello-mesothoracic suture............... sidalis, Ckh.
Anterior femur rufous where it touches tibia; pubescence of face white; no band of pubescence at scutello-mesothoracic suture .................... Casado, sp. n.

The following are new to the fauna of New Mexico:—

Megachile comata, Cress. 1872.
Tuerto Mountain, near Santa Fé, 8025 feet, Aug. 7, at flowers of Senecio (Ckh.).

Megachile pugnata, Say, 1837.
Five males from Santa Fé (Ckh.); one, July 11, at flowers of Lactuca pulchella; two at flowers of Rudbeckia laciniata, July 27 and Aug. 2; one, July 6; one, July 18.

Megachile latimanus, Say, 1823.
Three at Santa Fé (Ckh.); one ♀, July 25, at flowers of Sphalerea angustifolia; one ♂, Aug. 1, at flowers of Cleome serrulata; one ♂, Aug. 3, inside closed flower of Argemone platyceras.

Megachile texana, Cress. 1878.
Ruidoso Creek, 6400 feet, July 8, at flowers of Pentstemon, two females (E. O. Wooton).

Megachile Townsendiana, sp. n.
♂.—Length about 10½ millim.
Black, with scattered white pubescence. Head large, transversely oval; eyes sage-green; facial quadrangle a little longer than broad, perceptibly narrowed below; face (including clypeus) densely clothed with white hair; vertex strongly punctured, with very sparse white pubescence; cheeks sparsely pubescent above, densely clothed with white hair below; antennae black, flagellum slender, last joint not broadened; mandibles wholly black, the long hairs on their inferior margin whitish; mesothorax very strongly and
closely punctured; thoracic dorsum almost nude, the white
hairs few and scattered, except at the scutello-meso-thoracic
suture, where they are dense enough to form a band, and on
anterior part of mesothorax, where they form two obscure
sublateral longitudinal bands; tegula testaceous; wings
hyaline, nervures dark brown, second submarginal cell
receiving first recurrent nervure almost at its extreme base,
and second near its end; legs black, with white pubescence,
pale orange on inner side of tarsi; spurs whitish; all the legs
slender and simple; anterior coxae with the usual stout spines;
abdomen short and broad, rather shiny, strongly and closely
punctured, hardly at all pubescent, except that the hind
margins of the first four segments have dense white hair-
bands, the last being continued on to the base of the fifth;
sixth segment densely white-pubescent at base, at apex
narrowed, produced and emarginate, the outline being like
that of the two humps of a camel, but viewed from the side
the outline is that of a rose-thorn, the end being curved
downswards; beneath, the apex presents an obtuse median
prominence and a short tooth on each side, lateral of which
is an angle representing an incipient tooth; venter very
sparsely pubescent.

_Hab._ Las Cruces, New Mexico, Aug. 23, 1897, at flowers
of _Chrysopsis villosa_ in the _Larrea_-zone (C. H. T. Townsend).
Another, also from Las Cruces, is only 9 millim. long, but
evidently conspecific.

_M. Townsendiana_ by the shape of the apex of the abdomen
recalls _M. deflexa_, Cress., from Kansas, but in the latter the
tip is not emarginate and the mesothorax and vertex show
black hairs.

XXI.— _A North-American Freshwater Jellyfish._
_By Edward Potts.*_

On June 10, 1880, the first-known freshwater jellyfish
(Liminocodium Sowerbyi, Allman and Lankester) was dis-
covered in the Victoria Regia tanks in Regent’s Park, London.
Near the end of November 1884 a primitive “hydriform
organism,” from which it was supposed the jellyfish might
have been derived, was found in the same tanks and described
by Alfred Gibbs Bourne†.

* From _The American Naturalist_, December 1897, pp. 1032–1035;
communicated by the Author.
