XXXIX.—Contributions from the New Mexico Biological Station.—XII. On some Genera of Bees. By T. D. A. Cockerell and Emerson Atkins.

The family Stelidae of Ashmead consists of a series of parasitic bees which can hardly be grouped together in a classification based on actual blood-relationship. The subfamily Stelidinae appears to be an offshoot from the Anthidiinae; while it has been suggested that the other subfamily, Coelioxinae, is similarly related to the Megachilinae. The Coelioxinae, however, appear to be a composite group, Coelioxys and its allies being close to Megachile, while the genera with 4- to 6-jointed maxillary palpi must be referred to quite another series.

**Dioxy**s (Hoplopasites) producta, var. subrubra (Ckll.).

**Labial palpi.**—1 * longer than 2; 3 + 4 less than half length of 2.

**Maxillary palpi.**—Apparently 2-jointed; 1 oval, much longer than broad, 2 minute. There is presumably a basal tubercle, representing the true first joint, so that the palpi are properly 3-jointed.

**Galea.**—Slender, falciform, with transverse striae; inner margin ciliate.

Mr. Ashmead states that *Hoplopasites* is distinct from *Dioxy*, but no distinctive characters have been pointed out, nor have we found them.

The transverse striae on the galea are noteworthy, as they do not occur in the supposedly allied genera *Coelioxys* &c., but do occur in *Heriades* and *Chelostoma*.

* In this paper the figures in the descriptions of the palpi are to be understood to refer to the joints: thus, 1 = first joint.
some Genera of Bees.

Ileriades truncorum (L.).

Labial palpi.—1 much shorter than 2.
Maxillary palpi 3-jointed.

Chelostoma campanularum (Kirby).

Labial palpi.—1 extremely short, 2 very long; last joint only diverging from the straight line.
Maxillary palpi 3-jointed.

Phileremus mesilla, Ckll.

Labial palpi.—1 longer than 2; palpi shorter than in Dioxyx productus; 3 + 4 more than half length of 2.
Tongue very broadly fimbriate, the lateral fimbriae towards the tip longer than breadth of tongue at that point.
Maxillary palpi 2-jointed; 1 a low broad tubercle, 2 long-oval, rather large. The palpi look as if 1-jointed.
Galea.—Comparatively short and broad, broadly rounded at end, inner margin not ciliate; stria longitudinal.
The galea is wholly unlike that of Caelioxyx, Megachile, Dioxyx, &c., and resembles that of Epeolus. It seems likely that this and the Epeolus-like outward appearance of the bees are indications of real relationship.
This appears to fall in Phileremus as defined by Taschenberg, but it is by no means an Ammobates, of which Phileremus has been lately regarded a synonym. It accordingly finds no place in Ashmead’s tables.

Caelioxyx gilensis, Ckll.

Labial palpi.—1 shorter than 2; 3 + 4 not half length of 2.
Maxillary palpi 3-jointed; 1 a rounded tubercle; 2 broad, subquadrate viewed laterally; 3 rather small but stout.
Galea.—Long-falciform; stria oblique, decussating; inner margin ciliate. The mouth-parts confirm the view that this genus is closely related to Megachile.

Megachile apicalis, Spinola.

Labial palpi.—1 and 2 about equal, very much broadened, each with a row of strong bristles.
Maxillary palpi 3-jointed; 3 much longer than in Caelioxyx.
Galea.—Broad and tapering, with a margin on each side of the double rib. The inner area is rather narrow, decussated, and strongly ciliated on the edge; the outer area is broad, plain (not striated), and its edge is not ciliated. The rib bears a row of long bristles and shows some hyaline dots.
This differs from *Caelioxyx* in the greatly developed outer area of the galea; but this is only a specific character, as the following cases show:

**M. fortis.**—Decussated area much the broadest, plain area very small.

**M. fidelis.**—Plain area even more reduced.

**M. pugnata.**—Plain area on apical half a little larger than the decussated, but it is narrow below.

**M. manifesta.**—Plain area larger than the decussated.

**M. exilis.**—Plain area very narrow. (This species is peculiar for the maxillary palpi, which are covered with long bristles, and the third joint is remarkably long.)

**M. cleomis.**—Plain area almost as large as the decussated.

**Phileremulus nanus, Clkl.**

*Labial palpi.*—1 long, a little longer than $2 + 3 + 4$; 2 short, not very much longer than 3; 3 and 4 similar in character to 2. (Compare with *nomada*.)

*Tongue.*—Very long and slender, about twice as long as labial palpi. The tongue resembles that of *Allodape.*

*Maxillary palpi* 5-jointed; 1 broad and flattened; 2 long, cylindrical; 3 broader than 2 or 4; 5 somewhat constricted at middle. Measurements of joints in $\mu$:—(1) 15, (2) 66, (3) 27, (4) 24, (5) 66.

*Galea.*—Slender, falciform, sepia-colour, with the inner margin of apical half colourless; the sepia portion with minute hyaline dots; inner margin with few minute hairs.

**Neolarra pruinosa, Ashm.**

Description from material taken at Mesilla Park, N. M., May 7, on flowers of *Dithyrea Wislizenii.*

*Labial palpi.*—2 longer than in *Phileremulus* and nearly twice as long as 3.

*Maxillary palpi* 6-jointed; 4 broad at end; 6 very slender, only half as broad as 5. Measurements in $\mu$:—(1) 24, (2) 69, (3) 36, (4) 45, (5) 57, (6) 69.

*Neolarra* and *Phileremulus* agree nearly with *Allodape* in the mouth-parts. Smith figures, but does not count, a first joint in the maxillary palpus of *Allodape* similar to that of *Phileremulus*; on the other hand, he appears to count the long terminal joint as two. The habits of *Allodape* seem to resemble those of *Phileremulus.*
some Genera of Bees.

ASHMEADIELLA.

A. buconis, A. cactorum, and A. bigeloviiæ examined. Maxillary palpi 4-jointed. Galea very slender, deccussate.
In buconis and cactorum the first two joints of the labial palpi are very long and about equal; in cactorum the third joint is narrowly heart-shaped. In A. bigeloviiæ the first two joints of labial palpi are broadened and the first joint is noticeably longer than the second.

Ashmeadiella appears to be related to Osmia, but not to be much allied to Heriades or Chelostoma.

All the slides which form the basis of this paper were prepared by Mrs. W. P. Cockerell.

APPENDIX. By T. D. A. COCKERELL.

I would propose, in view of the above facts, to split up the Cœlioxinæ* of Ashmead (Tr. Am. Ent. Soc. xxvi. p. 80) into several subfamilies:

1. Cœlioxinæ proper, including Cœlioxys, to follow Megachilinae in the series.
2. Dioxinæ, including Dioxyæ (with Hoplothorax), position somewhat uncertain. The separation of this from Cœlioxinæ may perhaps be erroneous.
3. Philereminae, including Phileremus (sens. Taschenberg), to follow the series of Epeolus &c.†
4. Allodapinae, apparently including Allodape, Philermus, and Neolarra; but I know the first genus only from description.

This leaves numerous genera not accounted for; I do not place them, because I have no specimens, though their position can usually be guessed at.

Dioxyæ Martii, Ckll., sp. n.

♀.—Length about 7 millim. Black (without any red); pubescence about as in D. producta subrufa, the five hair-bands on abdomen very dense and white; legs black; tibial

* The Cœlioxynæ of Dalla-Torre and Friese is even more composite, including all the European parasitic bees except Psithyrus and Stelis. Ashmead (Tr. Am. Ent. Soc. xxvi. p. 53) has given an excellent criticism of this arrangement, and my only objection to his reforms is that they do not go nearly far enough along the lines he has indicated.
† Phileremus and Epeolus would form a more natural group than Epeolus and Nomada.
Bibliographical Notices.

spurs orange; antennæ formed and coloured as in _subrubra_, the flagellum ferruginous beneath; tegulae piceous, with a dark ferruginous patch; first recurrent nervure joining _first_ submarginal cell a little before its end; thoracic spine &c. as in _subrubra_; abdomen oval, not tapering apically, apical segment not produced. Otherwise about as in _subrubra_.

_Hab._ Picaecho Mountain, Mesilla Valley, New Mexico, March 25, 1900, at flowers of _Sphaeralcea Martii_. The plant was also new and was described in 'Botanical Gazette,' July 1901, p. 60.

East Las Vegas, New Mexico, U.S.A., Feb. 4, 1902.

BIBLIOGRAPHICAL NOTICES.

The present volume—the fourth in order of the complete series—is by Prof. Benham, who is to be congratulated on having fulfilled a very arduous task in a most successful manner. Singularly unattractive animals, and mostly parasitic in habit, it is not surprising that their study is attempted only by those keenly interested in the advancement of zoological science or in the investigation of the many and often very painful devastating diseases which are inflicted on mankind and the lower animals as a result of this parasitism.

Condensed into a surprisingly small compass, the author has contrived to embody practically everything that is known of these animals; so that this volume will form a source of reference of the highest value alike to the systematist, the morphologist, and the physician.

The historical sections of the various chapters are extremely interesting reading, and bear eloquent testimony to the extreme difficulty which besets the correct interpretation of the structure of these animals and the many pitfalls in the path of the investigator.

The _Mesozoa_ of Van Beneden are very fully dealt with in an appendix to the _Platyhelminths_, being regarded by the author as degenerate forms of this phylum—a view shared by Whitman and others—and therefore not needing the formation of a special grade to contain them. To this appendix the editor adds a very interesting paragraph on four new species of Orthonectids parasitic in _Chaetopods_ and Nemertines.

The work having been somewhat delayed in the press, a few notes have been added to the chapter on the _Nemertines_ by Mr. R. C. Punnett, of St. Andrews, in order to bring the work completely up
