Pest identification is the cornerstone of integrated pest management, but is a skill that can be difficult to master. Mistakes in identification are common, as many insects look and act alike, and/or can cause similar injury. Misidentifications could potentially lead to adverse consequences. A number of guides and websites can assist with insect identifications (e.g., bugguide.net is complete with color photographs and links to identification keys). In addition, several state and federal agencies have diagnostic labs to help assess suspected insect injury (for contacts in Utah, see page 6 of this fact sheet).

Here, we provide a quick identification reference guide for brown marmorated stink bug and Japanese beetle (both have been found in Utah) and emerald ash borer and Asian longhorned beetle (not yet detected in Utah). We focus on these four insects because they are often mistaken as other insects. We also briefly describe some similar species that can be mistaken for these insects. Note that this publication only covers the most common look-alike species and not ALL that resemble these invasives.

Insect look-alike species are sometimes other pests, but they can also be beneficial insects. For example, the spined soldier bug (Podisus maculiventris) is a beneficial, predatory stink bug (Fig. 2), but can be mistaken for the destructive and invasive brown marmorated stink bug (Halyomorpha halys). Similarly, the six-spotted tiger beetle (Cicindela sexguttata) is a predatory ground beetle (Fig. 3) that can be misidentified by some as the invasive Japanese beetle (Popillia japonica).

Invasive Insect Look-Alikes
Mistaken Insect Identity

Lori R. Spears, CAPS Coordinator • Ryan S. Davis, Arthropod Diagnostician • Ricardo A. Ramirez, Entomologist

Fig. 1. Proper species identification is key to effective IPM.

Fig. 2. The spined soldier bug is a beneficial, predatory stink bug that looks similar to the invasive brown marmorated stink bug.

Fig. 3. The six-spotted tiger beetle is a beneficial, predatory beetle, but can be mistaken for the invasive Japanese beetle.
Common Brown Stink Bugs (Euschistus spp.) (Fig. 8) are pests of fruit, seeds, grains, and nut crops. They are very common in Utah, and can be easily mistaken for BMSB.

Brown Marmorated Stink Bug (BMSB; Halyomorpha halys) (Figs. 4-6) is an invasive pest that is native to Asia and has been detected in 42 states, including Utah, in Salt Lake (since 2012), Utah (2013), Davis (2015), and Weber (2015) counties. BMSB is a significant pest of various crops, including fruits, vegetables, seeds, nuts, some field crops, and ornamental plants. It is also considered a nuisance pest as it overwinters in urban areas and releases a foul-smelling odor when disturbed or crushed.

Brown Marmorated Stink Bug Look-Alikes

Rough Stink Bug (Brochymena spp.) (Fig. 7) adults are considered both predators and pests, and are commonly mistaken for BMSB in Utah.

Fig. 4. BMSB adults are shield-shaped, 5/8-inch long, mottled brown, and have alternating dark and light bands on their antennae and along their abdominal edges (arrows in figure point to some of these features). The term “marmorated” means having a veined or streaked-like marble appearance.

Fig. 5. Other characteristics that distinguish BMSB from look-alike species include rounded shoulder tips and a smooth edge along their pronotum (shoulders).

Fig. 6. BMSBs have brownish-gray undersides.

Fig. 7. Rough stink bugs, unlike BMSBs, have a “tooth” on each side of the face, a heavily toothed shoulder, less distinct abdominal bands, and no dark and light antenna bands.

Common Brown Stink Bugs (Euschistus spp.) (Fig. 8) are pests of fruit, seeds, grains, and nut crops. They are very common in Utah, and can be easily mistaken for BMSB.

Fig. 8. Brown stink bugs are not as mottled in color as BMSBs, and have a small row of spines on the shoulders, no banding on the antennal segments, and a yellowish-green or pink underside (not shown in figure).

- Red-Shouldered Stink Bug (Thyanta custator)
Japanese Beetle

Japanese Beetle (*Popillia japonica*) (Figs. 9-10) is an invasive pest that is native to Japan. It has previously been found in Utah (Cache, Salt Lake, and Utah counties), but has been considered eradicated from the state. Despite this, reintroductions may occur at any time. Japanese beetles feed on more than 300 plant species, including numerous trees, ornamentals, vines, flowers, fruits, vegetables, weeds, and field crops.

**Fig. 9.** Adults are oval-shaped, 1/2-inch long, and have metallic green bodies, copper-colored wings, six white tufts of hair along each side of their body (including the tuft at the end of their wing covers), and clubbed antennae.

**Fig. 10.** Japanese beetles often congregate in groups.

Other scarab beetles, such as the False Japanese Beetle (*Strigoderma arbicola*), Hairy Bear Beetle (*Paracotalpa granicollis*), and Green Fruit Beetle (*Cotinis mutabilis*) (Figs. 11-12) are beetles that belong to the same family as the Japanese beetle and are common in Utah. False Japanese beetles are sometimes called sandhill chafers and rarely cause economic damage to crops. Hairy bear beetles feed on tree buds, blossoms, and leaves. Green fruit beetles feed on pollen, nectar, and petals, and overripe or damaged fruit, but are not known to cause damage to leaves, ripening and ripe fruit, or turfgrass.

**Fig. 11.** False Japanese beetles are dark tan to brown in color, and do not have distinct white hair tufts along their abdomens, as compared to the bright green and copper coloration and the distinct abdominal tufts of hair characteristic of Japanese beetles.

**Fig. 12.** Hairy bear beetles (left) and green fruit beetles (right) can be distinguished from Japanese beetles by the prominent fuzz along their abdomen and the yellow-orange stripe on their wings, respectively.

Emerald Ash Borer

Emerald Ash Borer (*Agrilus planipennis*) (Figs. 13-15) is an invasive beetle that is native to Asia and parts of Russia, and is considered to be the most destructive forest insect to ever invade the U.S. This beetle has not yet been found in Utah, but has been found in neighboring Colorado and much of the eastern U.S.

![Fig. 13](image1.png)
**Fig. 13.** Adults are metallic, green-colored beetles with a dorsoventrally flattened body.

![Fig. 14](image2.png)
**Fig. 14.** Adults have an iridescent purple abdomen beneath their forewings.

![Fig. 15](image3.png)
**Fig. 15.** Adults are about 1/2-inch long.

Emerald Ash Borer Look-Alikes

Flatheaded, Metallic Beetles (*Agrilus* spp.), such as the honeylocust borer (*A. difficilis*) and the bronze birch borer (*A. anxius*) (Fig. 16) are beetles that are closely related to the emerald ash borer, and are pests of honey locust and birch, respectively. Both species are common in Utah.

![Fig. 16](image4.png)
**Fig. 16.** Honey locust borers (left) have black bodies with white or yellow spots alongside their abdomen, whereas bronze birch borers (right) are more bronze in color.

Lilac-Ash Borer (*Podosesia syringae*) and Banded Ash Borer (*Neoclytus caprea*) (Fig. 17) look nothing like the emerald ash borer as adults. However, both species commonly infest ash trees, and are mistaken as emerald ash borer, so much so that we feel it is important to mention them.

![Fig. 17](image5.png)
**Fig. 17.** When lilac ash borers emerge from the tree, they leave irregularly round exit holes (1/4-inch wide) and protruding empty pupal cases (left). Banded ash borers emerge from oval exit holes (1/4-inch wide) (right). Emerald ash borers leave D-shaped exit holes (1/8-inch wide) when they emerge from trees, and do not leave behind pupal skins on the outside of the tree.

Asian Longhorned Beetle

Asian Longhorned Beetle (*Anoplophora glabripennis*) (Figs. 18-19) is an invasive beetle that originates from Asia, and is currently found in a few eastern U.S. states, but has not been found in Utah. Adults feed on living hardwood trees, including ash, birch, maple, elm, and willow.

Fig. 18. Adults are large (3/4 – 1 1/2-inches long) conspicuous beetles that have a glossy-smooth black body with irregular white spots, and a black scutellum (the region between the tops of the wings - note white arrow in figure).

Fig. 19. Adults have long black and white banded antennae that have 11 segments, each with a whitish-blue base. Some adults also have a bluish tinge to their feet.

Asian Longhorned Beetle Look-Alikes

White-Spotted Sawyer (*Monochamus scutellatus*) (Fig. 20) is a common wood-boring beetle found throughout the U.S., including Utah. This insect is not generally considered a pest, but closely resembles and is very commonly mistaken for the Asian longhorned beetle.

Fig. 20. White-spotted sawyers, unlike Asian longhorned beetles, have a dull or bronze-black body, faintly banded antennae, and white scutellum (the white spot located between the top of the wings - note the white arrow in figure). The number of white spots on the wing covers can vary between specimens.

Banded Ash Borer (*Neoclytus caprea*) (Fig. 21) is native to North America and is common in Utah. It is a pest of hickory, elm, and oak, but generally attacks only unhealthy trees.

Fig. 21. Banded ash borer adults are black with yellow or cream-colored markings on their wings and antennae that are less than 1/2 the length of their body.

Other Similar Species
