ACKNOWLEDGMENT

An expression of appreciation is extended to Dr. N. K. Roberts for his suggestions and patience during the course of this study, to Stewart Richards, who aided in the collection of the primary and secondary data, to the Bureau of Land Management and Forest Service for making funds available, to the Utah Experiment Station, that provided essential data, and to Dr. George T. Blanch and Dr. Reid Durtchi, members of my graduate committee for their time and consideration.

INTRODUCTION

Within the boundaries of Utah are approximately 52.7 million acres of land. About 41 million acres are rangeland, of which 73 percent is federally owned and 5 percent state owned (6). The portion owned by the Federal government is administered by the Bureau of Land Management (BLM) and the Forest Service. Most of this land is either arid or mountainous and has been used mainly for grazing in the past. It has other uses, however, such as mining, forestry, recreation, and watersheds. Due to recent increases in population, personal income, shorter work weeks, and improved transportation facilities, these alternatives are becoming strong competitors for the use of this land.

In Utah there are about 2,300 ranches using public range as part of their livestock feeding program. Approximately one-third of these use it on a year around basis (1).

Because of the multiple purpose nature of the public lands in Utah and the growing pressure from competing uses, the following questions have been raised: First, is the present use returning in revenues the true value of the resource? Second, is the present rate of use at a level that will facilitate the restoration, improvement, and maintenance of associated natural resources at their highest practical potential? Third, if adjustments are necessary, how will present users be affected?

1 Numbers in parentheses refer to references listed in the bibliography.
The proper fee level for grazing permits on Federal ranges has been a point of dispute ever since the first fees were instituted on forest ranges in 1905. The first established fees were 20 to 35 cents per head for cows and horses for the regular summer grazing season and 35 to 50 cents per head for the entire year. Fees were raised in 1910, 1915, and 1927 in an effort to make them represent more closely the value of the feed. In 1933 the present method of adjusting fees according to the market price of cattle was started (3).

Grazing fees on BLM land have had a similar evolution, beginning in 1936 when they were set at five cents per animal unit month (AUM). The present system of basing fees on the combined prices of cattle and sheep was established in 1958 (3).

The practice of adjusting permitted AUM's has been used by Federal agencies as a means of equating the number of animals using a particular range with the grazing capacity of that range. In Utah for the nine-year period of 1951 to 1959, public grazing permits were reduced approximately 10 percent, or 259,735 AUM's, on BLM range and 15 percent or 82,845 AUM's, on forest range (Appendix Table 14). Generally, a cut in permits has been enacted by reducing the number of animals allowed on the range for the grazing season or by shortening the grazing time allowed.

Through time several patterns of use have been established by ranchers on the public range. The predominant pattern among ranches in Utah has been to graze forest range in the summer and BLM range in the fall, winter, and spring.
Figure 1. Overall study area, Utah survey area, and native vegetation and ranching areas.
The purpose of this study was to determine the income effect of specified increases in fees and reductions in permitted AUM's on Utah cattle ranches using public range on an annual basis. This is only one part of a study in the Western States directed by the Economic Research Service of the Department of Agriculture to determine the effect of fee and permit adjustments on ranch operations which rely on public range for part of their annual feed supply. The overall study area is shown in Figure 2.

No previous work has been done in Utah on these problems, though some range economics studies have been made (2).

Regional studies were conducted in 1947 (9) and again in 1961 (10) by the United States Department of Agriculture's Economic Research Service on costs and returns of commercial cattle ranches in the Intermountain area, but they are too general to be of use in analyzing local problems. Work has also been done in the Northern Plains area on economics of cattle ranching (11) but conditions in this area are so different from Utah that the data are not comparable.

An economic framework and conceptual solution

The theoretical framework of the problem assumes the form outlined below (Figure 2).

![Figure 2. Envelope curve with three firm sizes depicted](image)
On the long run, the average cost curve (LAC) is superimposed on the short run average cost (AC) and marginal cost (MC) curves for firms of three sizes, assuming economies of scale. The firms are faced with a market price of $P$ which, under conditions of perfect competition, also equals the marginal revenue (MR) and average revenue (AR) curves for the firms. The vertical distance between the points where $MC = MR$ and the AC curve for each firm represents the average net revenue for that particular firm with the given cost and price conditions. This value multiplied by the number of units of output produced equals the total net revenue for the firms. If expenses increase with no change in product prices, the cost curves will shift upward, thereby decreasing net revenue, or if prices increase and expenses are constant, net revenue would increase also. A decrease in output initiates a movement to the left along the individual firm cost curves resulting in a reduced total net revenue.

In the context of the economic framework outlined above, the questions posed in this study were: First, what will be the effect of four alternative increases in fees on net income for three typical sized cattle ranches in Utah which use BLM range in the fall, winter, and spring and forest range in the summer? Second, with a 20 percent reduction in permitted AUM's, what will be the effect on ranch income? Assuming all other costs and revenues constant, raising fee levels would increase total costs and decrease net revenues in an amount equal to the change in fee expenses plus the change in interest on cash costs.

A reduction in permitted AUM's may be made in three ways: (a) reduce
the number of cattle permitted on the range; (b) shorten the grazing season; or (c) a combination of reducing grazing time and numbers of livestock permitted on the range.

In the short run four avenues are available for adjusting to a reduction in permitted AUM's: (a) cut herd size by selling cattle; (b) purchase feed, including hay, grain, or supplements, to fill the gap in the feeding program; (c) lease more land to make up the difference; or (d) use owned land to a better advantage.

Selling livestock would reduce both costs and revenues. The effect on net income would depend on which changes the most. With the other methods of adjustment revenues would remain constant or change very little and costs would increase. Purchasing feed would be the most expensive alternative.

If the grazing season were shortened, nothing would be gained by selling part of the herd but the other alternatives would still be applicable.

Cutting permitted AUM's by simultaneous reductions in time and numbers permitted would encourage essentially the same adjustments as when a reduction was made in time only.

**Empirical procedures**

A purpositive sampling procedure was used in collecting primary data. The samples in Utah using public land were stratified on a basis of seasonal grazing patterns, herd size, type of operation, and physical characteristics of the public land used. The survey area is shown by
barred portion of Figure 1. Data were gathered through personal interviews with ranchers. Secondary sources were relied upon for some of the cost and price estimates and inventory values. A budgeting procedure was used to determine the effect on ranch income resulting from changes in fees or a reduction in permitted AUM's.

Assumptions

The problem was limited to a short-run situation in which the rancher did not have time to sell out or change the size of his owned physical facilities. To test the economies of scale hypothesis, three ranch sizes were considered and designated as small, medium, and large.

A cattle ranch of the type included in this study was an operation on which a cow-calf-yearling herd was the principal enterprise.

An average level of management was assumed for a typical ranch of each size. Identical rates of crop and livestock production were assumed because of the close geographic proximity of the typical ranches and the similarity in management. A static ranch situation was also assumed in which there was no change in inventories of livestock, equipment or buildings and improvements between the beginning and end of the year. A constant level of technology was also assumed. Two alternative levels of cattle prices were used in the budgets; first, projected Ogden prices; and second, 1960 Ogden prices.

The order of presentation

The remainder of this study is divided into four parts. First is a description of the three typical ranches including size, management
characteristics, and internal structure will be presented. A description of the impact on costs and revenues of adjustments in fees and permitted AUM's will be included in the second and third parts. The last part will be the summary and conclusions drawn from the study. Only summary tables will be presented in the body. Details data are in the Appendix tables.
ORGANIZATION OF TYPICAL RANCHES

Although there is a wide variation in size among the typical ranches, they are in close agreement in their physical location, management practices, and internal structure.

Physical setting

Physiographically Utah is divided into three areas: the high Wasatch and Uintah mountains, the plateau region to the east and south of the Wasatch range, and the basin area extending from the mountains to the western borders of the state. Elevations range from 3,000 feet to heights of 6,000 and even 14,000 feet. Precipitation and temperature vary according to the altitude (5).

Between the desert floors and high mountain plateaus, vegetation belts have developed. On the high mountain slopes are conifers, aspens, many varieties of shrubs, perennial grasses and forbs (4). Dominating the lower more gentle slopes and high plains are sagebrush, junipers, rabbit brush, and various weeds and mixed grasses (7). Salt brush, shadscale, Russian thistle, and annual and perennial weeds comprise much of the desert vegetation (8).

Forage production is good at the higher elevations beginning in May and early June and continuing through August, September and into October, depending on when the snow comes.

Range at lower elevations, because of limited moisture, provides the best forage in the early spring and late fall and winter.
Though a large portion of the land is fertile, moisture deficiencies limit its use for agricultural purposes. Any form of agricultural activity other than livestock production is limited to selected valleys where irrigation projects are developed. In a few areas, however, rainfall is adequate to permit dry farming.

**Ranch size classes**

Using the number of breeding cows as an indicator of ranch size, the three predominant size groups in Utah were 40 to 60 head, 125 to 275 head, and 276 to 550 head of cows per ranch. The typical small ranch had 50 cows and the medium and large ranches 150 and 300 cows, respectively.

Size intervals were taken from a more inclusive study of Intermountain cattle operations using public range on an annual basis.

The distribution is skewed to the right and has one major mode (Figure 3). Forty percent of the operators had between 25 and 75 head of breeding cows, 22 percent had from 125 to 275 head of cows, and 10 percent had from 276 to 550 cows per herd.

**Ranch dependency on public grazing**

A primary consideration in this study was the importance of public grazing to the livestock feeding program. The extent to which all Utah cattle ranches of the type using public range the year around depend on BLM and forest permits for their feed supply was determined (Table 1). Dependencies on public range for the typical ranches studied were 54 percent for the medium and large sizes and 42 percent for the small.

Management practices

A cow-calf-yearling type operation was predominant on the typical ranches. Herds included mature cows and replacement heifers, bulls, the current year's calf crop, and yearling steers. The yearling steers were late born calves the previous year held over the winter to be grass fattened during the current summer.

Livestock sales were made in October and November, after the cattle came off the forest. The center of the production area was assumed to be approximately 200 miles from the terminal market at which the cattle were sold.

The breeding season started between April and June and continued to the last of November. One bull accompanied each 20 to 25 cows on the summer range. Bulls ranging on national forests must be of a "B" grade or higher. Typically, bulls were kept three years on the medium ranch and four years on the large and small ranches. On the medium and small ranches bull losses were negligible, but the large ranch had a 6 to 7 percent death loss each year.

Replacement heifers were selected in the fall from the spring calf crop. No replacements were purchased. The bases of selection were size, conformation, and general appearance. Heifers were bred to calve between two and three years of age.

Generally, calves were born from January to September. However, about 70 percent of the births took place before June. A count of the calves was taken in the spring and again in the fall when they came off
An 85 percent calf crop was typical on Utah ranches. This percentage was for both replacement heifers and cows.

Management practices not already discussed included control of insects and pests and disease prevention. Dipping was used most in controlling insects and pests. Since individual ranchers did not have the necessary facilities, dip vats were provided by local cattlemen's associations.

Blackleg and brucellosis were the most prevalent diseases guarded against. All new calves were vaccinated with a combination blackleg and malignant edema vaccine. Heifers were tested for brucellosis.

The annual feeding programs and calendars of operations for the typical ranches were similar. Both winter and summer feeding was centered around the use of public range. The cow herd ran on the forest from June to October and on BLM range from November to May. Some additional feeding of hay, grain, and a protein supplement was done in the winter. Replacement heifers, late calves, and yearling steers were mostly kept on private range and pasture with some supplemental feed during the winter months (Appendix Tables 15, 16, and 17).

The major winter operation was feeding and care of the livestock. Calving started between January and March. Seedbeds were prepared and crops planted in March and April. Irrigating was done from May to August. Generally, two crops of hay were harvested, one the last of June and the other the last of July or the first of August. The grain was also harvested during August. While cattle were on the forest in the summer, salt
was put out and some herding and fencing done. Local cattlemen's associations often supervised this work.

**Livestock inventories**

Herd inventories included mature cows, replacement heifers, steer and heifer calves, and bulls.

Although the same classes of livestock appeared on each ranch (Appendix Table 18), there was some variation in the internal structure of the herds (Table 2).

The difference between the bull:cow ratio on the large ranch and the medium and small ranches may be attributed to the bull death loss suffered on the large ranch making larger bull inventories necessary. A significant difference also existed in the percentage of replacement heifers to cows. Death loss may also be a contributing factor to this variation. A final difference was in the percentage of the calf crop held over and sold as yearlings. Each ranch was stocked with saddle horses but no work horses were reported.

**Land inventories**

Land inventories included irrigated cropland, native and improved meadows, and rangeland (Appendix Table 19). The large ranch had leased as well as owned rangeland. No leasing was done by the medium or small ranch.

Alfalfa and barley were the principle crops grown on the irrigated land. In localized areas other crops predominated but were not widely enough grown to be included as typical. The small ranch with almost

<sup>1/</sup> Over time there probably is bull death loss on small and medium ranches, but none was reported in the survey data.
twice the acreage of cropland per cow as the medium or large ranch was much more oriented to crop production.

**Buildings and improvements**

Little difference was found in inventories, construction, or condition of buildings and improvements among the typical ranches (Appendix Tables 20, 21, 22). Stock sheds, corrals, feed troughs and mangers, water troughs, culinary wells, and granaries comprised the major inventory items. Medium and large ranches also had a machine shed and shop. Pole and frame construction was common. Generally, the buildings were old. Most of the owned land was under fence.

The typical Utah cattle rancher lived in town and had his farmstead in the surrounding country which explains the absence of a house in the inventory of buildings.

**Machinery and equipment**

Since the ranches were oriented to a livestock operation, a minimum amount of tillage and cropping equipment appeared in the inventories (Appendix Tables 23, 24, 25). Tractors, trucks, pickups, and cars are found on the ranches. Standard haying equipment included a mower, side delivery rake, baler, and hay wagon. Other cropping equipment consisted of a plow, disk, harrows, ditcher, and manure spreader. Miscellaneous livestock and shop equipment were in the inventories also. Drilling and harvesting of grain crops was done through custom services.
Summary of investment

Total investment included the value of the land, grazing permits, buildings and improvements, machinery and equipment, and livestock (Table 3). The small ranch had $60,094, the medium ranch $123,790, and the large ranch $220,100 invested in these items.

On a per cow basis, the small ranch has a considerably larger total investment than the medium or large ranch (Table 4). It has approximately 40 percent more investment in land per cow than the other ranches and about four times more investment in machinery and equipment than the large ranch. The differences in investment per cow among the ranches suggest that economies of scale exist.
Labor requirements

The total labor used was 12.5 man-months, 17.2 man-months, and 28 man-months on the small, medium, and large ranches, respectively. (See Appendix Tables 26, 27, 28). It required 12.5 man-months of labor for 50 cows on the small ranch, while 5.7 and 4.7 man-months of labor were required for each 50 cows on the medium and large ranches.

The operator and his family provided most of the labor required. However, some hired day-labor was used on the small and medium ranches, while the large ranch employed one full-time worker. Generally, family labor was used full-time in the summer but only morning and evening during the school months. The small rancher had off-farm work about five months of the year.

Feed sources

All the hay and grain consumed was produced on the home ranch. Feed purchases consist of a protein supplement and salt (Appendix Tables 29, 30, 31). Frequently salt was used as a regulator in range feeding of supplements.

Sources of ranch income

Livestock and crop sales were the principal sources of revenue. Annual beef sales consisted of cull cows, calves, and yearling steers (Appendix Tables 33, 34). Calves weighed from 380 to 400 pounds and yearling steers about 600 pounds at sales time. Cull cows were generally those which were too old to produce or had some physical malfunction.

Crop sales consisted of hay and grain (Appendix Table 32). The amount sold was the excess over that which was consumed by the livestock and would vary each year according to their needs.

Costs and expenses

Costs and expenses included all cash outlays and the value of all items for which no direct cash payment was made (Appendix Table 35). Most of the items have been taken from previously discussed tables and are explained there.

Repairs and maintenance of machinery and equipment constituted the largest cash expense on the medium and small ranches. Labor expense had this distinction on the large ranch. Labor costs increased markedly between the medium and large ranches because the latter uses full-time hired help while the former gets by with small amounts of day-labor.
Grazing fees were 5 percent of the cash costs on the small ranch and 8 percent and 7 percent on the medium and large ranches. The large ranch had range lease expenses as well as grazing fees to pay.

Total cash costs were $3,613 for the small ranch, $6,118 for the medium ranch, and $14,217 for the large ranch.

Depreciation was the major non-cash cost. The straight-line method was used in arriving at the depreciation values. Depreciation was figures on bulls and horses because they were purchased as capital investments.

Interest on cash costs amounted to 6 percent for 6 months while the rate on capital investment was 5 percent per year.

Payment made to the operator and his family for their labor contribution was based on the wage rates for full-time and part-time labor.

Total ranch costs were $12,065, $20,938, and $36,287 for the small, medium, and large ranches, respectively.

Income and expense summary

Based on projected net cattle prices at Ogden, the small ranch lost $135 and the medium and large ranches made $2,162 and $4,963, respectively, in terms of net income (Table 5). Using net prices at Ogden in October 1960, net income for the small ranch was $166, the medium ranch $3,029, and the large ranch $6,783 (Table 6).

That the small ranch was more crop oriented is illustrated by the fact that 32 percent of its receipts came from crop sales while 13 percent

---

2See footnote 1, Appendix Table 33, for an explanation of how net projected prices are derived.

3See footnote 1, Appendix Table 34, for derivation of net October 1960 Ogden prices.

</table>
and 18 percent, respectively, of the receipts on medium and large ranches were from this source.

Cash costs constituted a larger percentage of total costs on the large ranch than on the medium or small ranches.

**Comparative summary**

Of the typical ranches, the small size got the most production per cow. This was expected since it sold a larger percentage of its calf crop as yearlings than did the medium or large ranch. Beef production per animal unit on the small ranch, however, was lower than on the other ranches because a larger percentage of the total herd were replacements and young stock (Table 7).

Gross ranch income per cow relative to beef sales per cow reflected the influence of crop sales on the ranch income. Crop production was much more important on the small ranch than on the medium or large ranch.

Expenses as well as income per cow were larger on the small ranch. Although it got the most production per cow, this production was more than offset by the costs. Medium and large ranches, while having lower rates of production, through more efficient use of their facilities, were able to produce at a much lower cost per unit and were making positive net returns per cow.

Using 1960 prices, net income per cow was $3 for the small ranch, $20 for the medium ranch, and $23 for the large ranch (Table 8).

FEE ADJUSTMENTS

Four alternative levels of fees for BLM and Forest Service permits were budgeted through on the typical ranches (Appendix Tables 36, 37, and 38). The impact on costs and income was limited to changes in actual fee expenses, interest on cash costs, and net income. Gross income did not change.

The degree of the impact on costs was reflected in the relative importance of fees to total cash costs before and after the budgets were made (Table 9).

Although of little significance initially, fees became a major expense item at higher levels. Effects on net income were of no small consequence. Based on projected net prices, a 68 percent decrease on the medium ranch and a 52 percent decrease on the large ranch resulted.
When 1960 net prices were used, the decrease was 47 percent on the medium ranch and 38 percent on the large ranch. Raising fees had less impact on net ranch income at the higher cattle prices (Table 10).

PERMIT ADJUSTMENTS

Adjustments in permitted AUM's may be made by reducing the number of livestock permitted, by reducing the grazing period, or by a combined adjustment in time and numbers.

Reduction in numbers

When a 20 percent reduction in permitted AUM's was instituted and the reduction was made in numbers of livestock allowed on the range, the influence each alternative adjustment to this reduction had on costs and revenues determined the degree of acceptability of that alternative (Appendix Tables 39, 40, 41).

In the short run, possible adjustments to a cut in permits were: (a) reduce the herd size; (b) purchase feed; (c) lease land; (d) change the use of owned land (Tables 11, 12).

Large and medium ranches had similar reactions to these alternatives, while those of the small ranches were different. Differences in internal ranch structure accounted for the various reactions.

Any deviation from the initial ranching program was detrimental to the medium and large ranches. With the existing level of management and technology Federal ranges provided the cheapest source of feed available to them. Two alternatives were better for the small ranch; both emphasized crop sales.

Reducing the herd size was best for the medium ranch and second best for the small and large ranches. Because of fixed costs, as herd

1/ Taken from Appendix Tables 39, 40, and 41.
size decreased, costs per unit increased, making this less desirable than the initial program. An interesting adjustment took place on the small ranch relative to this alternative. As herd size decreased, net losses decreased also. This may be attributed in part to the influence of the crop enterprise on the ranch operation and in part to the relative magnitude of the product prices. It would probably pay the small rancher to reduce his herd and increase crop sales until all crops produced are sold and his owned range and pasture and public grazing permits can fully support his herd.

Purchasing feed which included hay, grain, or concentrates, was the least desirable method of adjusting to a reduction in permits. It was the most expensive alternative and since total revenue did not change but costs increased considerably, a substantial decrease in net revenue resulted.

Leasing land was best for the large ranch and the second and third best alternative for the medium and small ranches, respectively.

In budgeting through a change in the use of owned land, the same adjustment was made on all three ranches. The cropping program was altered so one-fifth of the cropland was in grain and the rest in alfalfa. With existing prices and yields, hay production was the more profitable enterprise. The change in the cropping pattern increased the production and sales of hay which in turn increased net income from crops. For the small ranch this proved to be the best adjustment to a reduction in permits.

**Effects of variable pricing.** With net October 1960 livestock prices, there was no change in the comparative desirability of the adjustments
to a reduction in permitted AUM's (Table 13). However, the degree of acceptability of the adjustments did change. There was less inclination to reduce the number of livestock on the ranches and variation in the effects on net income of the alternatives becomes smaller.

Reduction in grazing time

If a reduction in permitted AUM's was made in time, there was no gain made by selling cattle. The necessary adjustment was simply one of finding other sources of feed for the period of time they had been cut off the public range. The impact on costs and revenues when the alternative adjustments were budgeted through would be no different than if the cut had been taken in number of livestock permitted.

Simultaneous cuts in permitted AUM's and increases in fees

Increasing fees and reducing permitted AUM's at the same time had a magnified effect on net ranch income (Appendix Tables 42, 43).
With net projected livestock prices, the small ranch, by selling cattle, could maintain an income comparable to that of the initial program through one increase in fees. By changing the use of its owned land, the small ranch could absorb three increases in fees without suffering greater losses in net income.

Using net 1960 cattle prices, selling livestock would not maintain net income through one fee increase. However, changing the use of owned land more than supported a net income comparable with the original through three increases in fees.

There were 25 possible net revenues for each ranch when all combinations of fee levels and adjustments to a reduction in permitted AUM's were budgeted through. With the exception of those mentioned in the previous paragraphs, all the combinations would have a depressing effect on net income.
SUMMARY AND CONCLUSIONS

The purpose of this study has been to determine the effect of cutting grazing permits and increasing grazing fees on net income of Utah cattle ranches which use public range for grazing the year around.

Fee expenses were a relatively small percentage of the cash costs on the typical ranches studied. Small increases in fees changed the ranch financial picture very little, however, as the value of the fees increased they became more important relative to other cash costs until at the higher levels they were one of the major cost items.

The effects of a reduction in permitted AUM's varied with the ranch size, its internal structure, and the type of adjustments made to offset the permit reduction. If each ranch used the best of the alternatives available to adjust to a reduction in AUM's, the economic status of the ranch would change little.

The typical small ranch was actually better off when its permits were cut, providing the adjustments to the reduction were made by selling cattle or altering the cropping pattern on the owned land. Purchasing feed or leasing land would be more expensive but the increase in costs would be small.

Any reduction in AUM's would have an adverse financial effect on the typical medium and large ranches. Leasing land would be the most favorable adjustment on the large ranch while reducing the herd size would be best for the medium ranch. Reorganizing the use of owned land on these ranches had little positive effect with the existing
level of management and technology. Utah cattle ranches were losing substantial sums of money on a per cow basis when all costs were included. Raising fees and cutting permitted AUM's would accentuate the problem, the degree would be directly associated with the magnitude of the change in fees and permitted AUM's.

This study has been limited to the short run effects on ranch income of raising fees and cutting permits with management and technology held constant. More research needs to be done on possible long run adjustments open to ranchers. Also, an evaluation of the effect of various levels of management and technology on the economic well being of Utah cattle ranches would be helpful.

1/ 2 years old and over.

The inventory values of cows, yearlings, and calves are based on the 1960 market price at the ranch.

The inventory value of bulls and horses is the market value plus the salvage value divided by 2.
