Abstract
Fire blight caused by the bacterium Erwinia amylovora results in millions of dollar in losses worldwide. It is the most important disease problem for apple and pear growers in Utah. Currently the only effective management strategy is application of the antibiotic streptomycin. In 2006, resistant isolates were detected in an apple orchard in Utah County. To determine the distribution of resistant isolates, samples collected in 2006, 2007, 2010 and 2011 from orchards across Utah were tested for resistance to streptomycin. Isolates were screened at 0, 100 and 1000 ppm of streptomycin. For each isolate there were 3 plates: water control, 100ppm, and 1000ppm of streptomycin. After 24 hours plates were evaluated. A halo indicated the isolate was sensitive and no halo indicated resistance to streptomycin. The bacteria were quantified to a concentration of 1x10^8 bacteria. 100 microliters of the bacterial suspension were spread onto LB plates. A 10mm hole was cut in the center of each plate and filled with diluted streptomycin. For each isolate there were 3 plates: water control, 100ppm, and 1000ppm of streptomycin. After 24 hours plates were evaluated. A halo indicated the isolate was sensitive and no halo indicated resistance to streptomycin. The rpsL gene of resistant isolates was sequenced and compared to sensitive isolates to determine if a mutation was present. rpsL sequences were edited and then aligned in Clustal W.

Materials and Methods
E. amylovora isolates were streaked onto CCT plates. The bacteria were boiled in water for 3-4 minutes to release DNA. PCR was conducted, using E. amylovora-specific primers (3) to verify the ID. The DNA bands were extracted from electrophoresis gels (Qiagen Gel Extraction Kit) and sequenced at The University of Arizona genetics core lab. Sequences were compared with E. amylovora sequences in the NCBI Genbank database. Each isolate was tested for streptomycin resistance. In addition, isolates from 2006 and 2007 from the same locations were also tested. The bacteria were quantified to a concentration of 1x10^8 bacteria. 100 microliters of the bacterial suspension were spread onto LB plates. A 10mm hole was cut in the center of each plate and filled with diluted streptomycin. For each isolate there were 3 plates: water control, 100ppm, and 1000ppm of streptomycin. After 24 hours plates were evaluated. A halo indicated the isolate was sensitive and no halo indicated resistance to streptomycin. The rpsL gene of resistant isolates was sequenced and compared to sensitive isolates to determine if a mutation was present. rpsL sequences were edited and then aligned in Clustal W.

Introduction
Fire blight is a disease of apples, pears and other rosaceous plants. The disease is caused by the bacterium Erwinia amylovora. The bacteria survive the winter in cankers and enter the plant through natural openings or wounds. Fire blight is the most important disease problem for Utah apple and pear growers. To manage the disease streptomycin is used as the most effective treatment. In recent years, streptomycin-resistant isolates have been found across the United States including Utah (1; 2). There are at least two mechanisms for resistance development: 1. a single base pair mutation in the rpsL gene. With the mutation streptomycin can no longer bind to S12 protein encoded by the rpsL gene and 2. the acquisition of a plasmid containing StrA-StrB gene complex.

Results and Discussion
I isolated E. amylovora from approximately 107 symptomatic trees from Utah County and 90% of the isolates were tested for the rpsL gene. From those 90% all of them showed the same mutation in the gene on codon 43. 15 trees were sampled from the Cache County area and only one had Erwinia. The 2006 and 2007 isolates were sent off for sequencing and came back with the same mutation. Majority of the isolates in Utah had a mutation in codon 43 which results in streptomycin resistances. The mutation changes the amino acid from a lysine to an arginine. Comparing the recent 2011 isolate with the 2006 isolates it is confirmed that the mutation is persistent even after streptomycin has not been used for years. Few isolates have not been identified due to a different mutational mechanism.
