

## How To Create A Lie Algebra

### Synopsis

- We show how to create a Lie algebra in Maple using three of the most common approaches: matrices, vector fields and structure equations.

### Examples

Load in the required packages.

```
[> with(DifferentialGeometry): with(LieAlgebras):
```

#### Example 1.

The well-known Pauli matrices (upon multiplication by I) are a set of 3 anti-Hermitian matrices which define a real 3-dimensional matrix algebra. Here are the Pauli matrices:

```
[> A := [Matrix([[0,I], [I,0]]), Matrix([[0, 1], [-1, 0]]), Matrix([
  [I, 0], [0, -I]])];
```

$$A := \left[ \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \begin{bmatrix} I & 0 \\ 0 & -I \end{bmatrix} \right] \quad (1)$$

The Lie algebra bracket is the matrix commutator. The output of the command [LieAlgebraData](#) is a list of the non-zero brackets, where by default  $e1, e2, e3$  denote the 1st, 2nd and 3rd Pauli matrices.

```
[> LD1 := LieAlgebraData(A, Alg1);
      LD1 := [[e1, e2] = -2 e3, [e1, e3] = 2 e2, [e2, e3] = -2 e1] \quad (2)
```

We use the command [DGsetup](#) to store these structure equations in memory.

```
[> DGsetup(LD1);
      Lie algebra: Alg1 \quad (3)
```

At this point one can now invoke many of the commands in the [LieAlgebras](#) package. For example, here is the [Killing](#) matrix for this Lie algebra:

```
[Alg1 > Killing(Alg1); \quad (4)
```

$$\left[ \begin{array}{c} \\ \\ \\ \end{array} \begin{array}{ccc} \begin{bmatrix} -8 & 0 & 0 \\ 0 & -8 & 0 \\ 0 & 0 & -8 \end{bmatrix} \\ \\ \\ \end{array} \right] \quad (4)$$

### Example 2.

The infinitesimal generators for translations and rotations in the  $xy$  plane are vector fields which define a 3-dimensional Lie algebra. The bracket operation is the Lie bracket of vector fields. We create a coordinate system for the  $xy$  plane, define the vector fields and compute their brackets.

$$\left[ \begin{array}{c} > \text{DGsetup}([x, y], R2); \\ \\ \end{array} \begin{array}{c} \\ \text{frame name: } R2 \\ \end{array} \right] \quad (5)$$

$$\left[ \begin{array}{c} R2 > \text{EuclideanGenerators} := [D_x, D_y, xD_y - yD_x]; \\ \\ \end{array} \begin{array}{c} \\ \text{EuclideanGenerators} := [D_x, D_y, xD_y - yD_x] \\ \end{array} \right] \quad (6)$$

$$\left[ \begin{array}{c} R2 > \text{LD2} := \text{LieAlgebraData}(\text{EuclideanGenerators}, \text{Alg2}); \\ \\ \end{array} \begin{array}{c} \\ \text{LD2} := [[e1, e3] = e2, [e2, e3] = -e1] \\ \end{array} \right] \quad (7)$$

The labels of the basis of the Lie algebra can be specified when the Lie algebra is initialized with *DGsetup*. Here we use  $X, Y, R$  as labels for the 1st, 2nd and 3rd vectors in the Lie algebra and  $\alpha, \beta, \theta$  as the labels for the dual 1-forms.

$$\left[ \begin{array}{c} R2 > \text{DGsetup}(\text{LD2}, [X, Y, R], [\alpha, \beta, \theta]); \\ \\ \end{array} \begin{array}{c} \\ \text{Lie algebra: } \text{Alg2} \\ \end{array} \right] \quad (8)$$

Here is the multiplication table - the table of brackets - for the Lie algebra.

$$\left[ \begin{array}{c} \text{Alg2} > \text{MultiplicationTable}(\text{"LieTable"}); \\ \\ \end{array} \begin{array}{c} \\ \begin{array}{c|ccc} & X & Y & R \\ \hline X & 0 & 0 & Y \\ Y & 0 & 0 & -X \\ R & -Y & X & 0 \end{array} \\ \end{array} \right] \quad (9)$$

We can use the [Query](#) command to check that this Lie algebra is solvable.

$$\left[ \begin{array}{c} \text{Alg2} > \text{Query}(\text{"Solvable"}); \\ \\ \end{array} \begin{array}{c} \\ \text{true} \\ \end{array} \right] \quad (10)$$

### Example 3.

An abstract Lie algebra can always be created by specifying the non-zero Lie brackets. In the following  $[x1, x2, x3, x4, x5]$  are unassigned names which denote the basis elements for the Lie algebra, which is defined by the following brackets.

```
Alg2 > StrEq := [[x2, x3] = x1, [x2, x5] = x3, [x4, x5] = x4];
StrEq := [[x2, x3] = x1, [x2, x5] = x3, [x4, x5] = x4] (11)
```

We convert the brackets to a Maple Lie algebra data structure with *LieAlgebraData* and initialize with *DGsetup*.

```
> LD3 := LieAlgebraData(StrEq, [x1, x2, x3, x4, x5], Alg3);
LD3 := [[e2, e3] = e1, [e2, e5] = e3, [e4, e5] = e4] (12)
```

```
Alg2 > DGsetup(LD3);
Lie algebra: Alg3 (13)
```

The command [Derivations](#) calculates the Lie algebra of infinitesimal automorphism of a Lie algebra. It is just one of many ways to create a new Lie algebra from a given one.

```
Alg3 > Derivations(Alg3, "Full");
[[ [ [ 1 0 0 0 0 ], [ 0 1 0 0 0 ], [ 0 0 0 0 0 ], [ 0 0 1 0 0 ], [ 0 0 0 0 0 ],
[ 0 1/2 0 0 0 ], [ 0 0 0 0 0 ], [ 0 0 0 0 0 ], [ 0 0 0 0 0 ], [ 0 0 0 0 0 ],
[ 0 0 1/2 0 0 ], [ 0 0 0 0 0 ], [ 0 1 0 0 0 ], [ 0 0 0 0 1 ], [ 0 0 0 0 0 ],
[ 0 0 0 0 0 ], [ 0 0 0 0 0 ], [ 0 0 0 0 0 ], [ 0 0 0 0 0 ], [ 0 0 0 1 0 ],
[ 0 0 0 0 0 ], [ 0 0 0 0 0 ] ],
[ [ 0 0 0 0 1 ], [ 0 0 0 0 0 ],
[ 0 0 0 0 0 ], [ 0 0 0 0 0 ],
[ 0 0 0 0 0 ], [ 0 0 0 0 1 ],
[ 0 0 0 0 0 ], [ 0 0 0 0 0 ] ] ] (14)
```

## Commands Illustrated

- [LieAlgebras](#), [Derivations](#), [DGsetup](#), [LieAlgebraData](#), [Killing](#), [MultiplicationTable](#), [Query](#)

## Related Commands

- The following commands provide additional ways to create Lie algebras: [Derivations](#), [InfinitesimalHolonomy](#), [InfinitesimalSymmetriesOfGeometricObjectFields](#), [KillingVectors](#), [LieGroup](#), [SimpleLieAlgebraData](#), [StandardRepresentation](#), [SymbolAlgebra](#)
